4. Finally, and as a deduction from these facts, the contrast between the action of cocaine and that of curare; the former exerting its influence upon the sensitive nerves; the later upon the motor nerves.

M. Laborde confirmed the investigations of Laffont, and suggested that there was a true physiological antagonism between cocaine and curare.

Extraction of the First or Sixth Year Molar.

In a paper in the *Independent Practitioner*, February, 1888, on the extraction of the first or sixth year molars, Dr. G. W. Weld makes the following points with reference to it:

1. Its title to longevity can only be questioned under neglect and abuse. 2. It is the keystone molar; with it the integrity of the arch is preserved; without it the usefulness of the arch is impaired, if not destroyed. 3. Its extraction at an early period signifies a loss of masticating surface that is absolutely detrimental to the health and comfort of the patient in early life. 4. In view of the prominent position it occupies in the arch and its relation and influence as a just poise or balance in the distribution of the varied strains incident to mastication, its extraction can only be considered a physiological mistake.

Physostigmin in Chorea.

L. Riess reports, in the *Berliner klin. Wochenschrift*, No. 22, 1887, the result of his treatment of chorea and other hyperkinetic affections with physostigmin. He has obtained successful results from hypodermic injections of $\frac{1}{60} - \frac{1}{20}$ of a grain several times a day. The duration of the disease was shortened in nearly all cases, and recovery sometimes occurred in five days. With the exception of vomiting, no bad effects of the drug were observed.

Cocaine as a Means of Differential Diagnosis.

In a communication to the *Wiener med. Wochenschrift*, No. 44, 1887, Baumgarten expresses the opinion that if an infiltration in the larynx subsides for some time after being painted with cocaine, the diagnosis can be made of a catarrhal trouble. But if the cocaine produces no diminution in the swelling, nor paleness, then the disease is to be regarded as serious; and if no diminution in swelling, nor pallor, occur even after some days, then catarrhal troubles can be excluded.

Early Appearance of Menopause.

Dr. I. K. Frazer communicates to the Texas *Courier of Medicine*, February, 1888, the notes of a case in which the menopause was apparently established at the early age of nineteen years. He is unable to assign a cause for this result, as the general health seems perfect.

Lunacy in Scotland.

The twenty-ninth annual report of the Lunacy Board for Scotland deals with the statistics of lunacy from 1858 to 1887, from which it appears that the number of pauper lunatics in asylums had increased up to 1882, when it stood at 188 per 100,000. Last year the number fell to 184. The number of private lunatics in establishments reached 39 per 100,000 in 1881, and now stands at 38. There had been a steady annual increase up to 1882.

Toothache.

Dr. Popoff, writing in the *Russkaya Meditzina*, states that he has succeeded in relieving toothache caused by caries of the teeth by making the patient rinse the mouth every half-hour with a dessertspoonful of a twenty per cent. solution of permanganate of potash, taking care to hold the liquid in the mouth for some minutes.

Simple Prescription for Small-Pox.

The *Chemist and Druggist* says that Sheffield chemists have of late had quite a run on the following prescription:

Cream of tartar	1 oz
Powdered rhubarb	14 grains

It seems that a clergyman, in a letter written to a Leeds newspaper, had recommended it as an infallible remedy for, and preventive of, small-pox. The Sheffield papers copied his letter, and rhubarb and cream of tartar now hold the field.

Pruritus Vulvæ following Leucorrhœa.

Verrier recommends the following solution:

Carbolic acid	9 minims
Acetate of morphine	7 grains
Dilute hydrocyanic acid	50 minims
Glycerine	3 drachms
Water	4½ ounces

After the parts have been washed and allowed to dry, they should be dusted with powdered starch. If the pruritus still persists, insert a cotton tampon, wet with the above solution, between the lips of the vulva, and secure it with a bandage.—*Union Médicale du Canada*, February, 1888.

Formula for Dysmenorrhœa.

L'Union Médicale du Canada says that Calvin's formula is:

Tincture of gelsemium,
Camphor water,
Deodorized tincture of opium...āā..f℥ij
Mix. Dose, 30 drops every two hours.

Asymmetry of the Face.

Hasse has made an interesting observation upon asymmetry of the face. He had found that the famous statue of the Venus of Milo is executed with anatomical accuracy in all essential particulars; but Henke, on the contrary, found fault, among other things, with the obliquity of the face of the Venus. Hasse has subsequently made the surprising statement that not only the Venus of Milo, but all of us have oblique faces. This asymmetry is confined to the upper half of the face, the mouth and chin being completely symmetrical. As a rule, the left half of the skull predominates, in consequence of the stronger development of the left half of the brain, and the nose, as we all know, deviates to the right or left. Moreover, the region of the right eye is generally higher than that of the left, while the left eye is nearer the median line. The left ear, as a rule, is higher than the right. These opinions are supported by reproductions of photographs of the Venus and of living men and women.—*Deutsche med. Wochenschrift.* February 16, 1888.

The Last of another Anæsthetic Alkaloid.

There appears great reason to conclude that "drumine," an alleged anæsthetic alkaloid derived from the *euphorbia Drumondii*, is not only not an anæsthetic, but is not even an alkaloid. It seems to be a compound made up in great part of calcium oxalate. Such at least is the conclusion pointed to by the investigations of several contributors to a recent issue of the *Pharmaceutical Journal and Transactions*. Moreover, it is announced that the purveyors of "drumine," having found it unsatisfactory, no longer furnish it. It will be remembered that "drumine" was brought into notice by Dr. John Reid, of Melbourne. Its career is not unlike that of "gleditschine." Some of our European contemporaries have seen fit to speak of the "gleditschine" affair as "an American swindle." The *Bulletin général de thérapeutique*, commenting on the matter of "drumine," more politely refers to it as "*une mystification*," without any adjective denoting its Australian origin.—*N. Y. Med. Journal*, Feb. 11, 1888.

Compulsory Vaccination.

The following extract from *The Sanitarian* would seem to indicate that a compulsory vaccination law has its advantages: "The success of the anti-vaccinationists is aptly shown by the results in Zurich, Switzerland, where for a number of years, until 1883, a compulsory vaccination law obtained, and small-pox was wholly prevented (not a single case occurred in 1882). This result was seized upon in the following year by the anti-vaccinationists, and used against the necessity for any such law, and it seems they had sufficient influence to cause its repeal. The death returns for that year (1883) showed that for every thousand deaths two were caused by small-pox; in 1884, there were three; in 1885, seventeen and in the first quarter of 1886, eighty-five.'

Reception to Prof. Agnew.

A reception by the Alumni of the Medical Department of the University of Pennsylvania and the three undergraduate classes will be given to Prof. Agnew, on Tuesday, April 24, 1888, in honor of the fiftieth anniversary of his graduation. Those desiring to participate should communicate with Dr. Tyson, at the University.

Prof. Unna's Practical Course in Dermatology.

American medical men who are to be in Europe this year may be interested to learn that Prof. P. G. Unna, of Hamburg, intends to give a six months course on practical dermatology, beginning early in April, in which he expects to cover the whole ground of the histology, bacteriology, diagnosis and therapeutics of skin-diseases.

In a circular announcing this fact, Dr. Unna states that he hopes that his instructions, backed by the use of his abundant clinical material, will add to this specialty efficient young forces.

Medical Society of the State of Pennsylvania.

The Thirty-ninth Annual Meeting will be held in Philadelphia, on Tuesday, Wednesday, Thursday and Friday, June 5, 6, 7 and 8, 1888, commencing on Tuesday, June 5, at 9 A. M.

Appointments for 1888.—Address on Practice of Medicine: Dr. E. R. Mayer, of Wilkesbarre; address on Surgery: Dr. Jas. McCann, of Pittsburg; address on Obstetrics: Dr. Theophilus Parvin, of Philadelphia: address on Mental Disorders: Dr. Horatio C. Wood, of Philadelphia; address on Otology: Dr. B. A. Randall, of Philadelphia; address on Hygiene: Dr. Traill Green, of Easton.

Resolutions to be acted upon.—1. Offered by Dr. S. Solis Cohen, of Philadelphia:—"There shall annually be constituted, as the first item of business at the afternoon session of the first day, a Nominating Committee, to consist of one member named by the majority vote of the delegation of each county, who shall report, as the first item of business in the afternoon session of the second day, a list of candidates for officers and necessary committees. In the Nominating Committee each member shall cast a number of votes equal to the number of delegates from the county in actual attendance upon the session."

2. Offered by Dr. A. Enfield, of Bedford:—"The time and place of meeting shall be determined by the Nominating Committee, and the sessions shall always begin at 9 A. M., and continue for four days; and the Committee of Arrangements shall adjust papers, etc., in accordance with this by-law."

3. Offered by Dr. A. M. Pollock, of Pittsburg:—"That the Censors of the appropriate district shall have power to determine whether a resident of one county shall be entitled to become a member of an adjacent county society which may be more convenient for him to attend."

Applications to read papers at this session should be sent *not later than April 15*, to Dr. John H. Packard, Chairman of Committee of Arrangements, 1926 Spruce street, Philadelphia.

Secretaries of County Medical Societies are earnestly requested to forward at once complete lists of their officers and members, giving the post-office address of each.

Every delegate, before admission, must present a certificate of delegation, signed by the President or Secretary of his County Society. Every permanent member (not a delegate), before admission, shall present a certificate of good standing in his County Society.—(*Extract from the Constitution.*)

Railroad facilities will be announced when obtained. All who desire excursion orders should notify the permanent Secretary, Dr. William B. Atkinson, Philadelphia, stating which railroad must be used.

Association of American Medical Editors.

The next meeting of the Association of American Medical Editors will be held in Cincinnati, Monday evening, May 7. After the address of the President, Dr. William Porter, of St. Louis, the Association will consider a plan of organization reported by a committee of which Dr. McMurtry, of Danville, Ky., is chairman. Officers for the ensuing year will be elected, and the Association will then discuss the following questions:

1. Is the multiplicity of medical journals an advantage to the profession? To be discussed by Drs. Crothers, Hartford; Sim, Memphis; Wile, Conn.; Love, St. Louis; Culbertson, Cincinnati; Cushing, Boston; Coomes, Louisville, and Gray, Chicago.

2. How far do medical journals distributed by drug houses and manufacturers interfere with regular medical journalism? To be discussed by Drs. Reynolds, Louisville; Davis, Chicago; Shoemaker, Philadelphia; Bond, St. Louis; Connor, Detroit; Kiernan, Chicago; Thacker, Cincinnati, and Fulton, St. Paul.

NEWS.

—A new medical club, called the "Galen Club," has been founded in London.

—Dr. Charles Croker King died in London, February 25, of gangrene of the foot.

—A polyclinic has been organized in New Orleans. The first course of lectures will begin April next.

—The Fothergill prize of the Medical Society of London has been awarded to Dr. Hobart A. Hare, of Philadelphia.

—Dr. W. W. Godding, of Washington, thinks there is no truth in the popular belief that fish is of value as a brain food.

—Dr. Bayley Balfour has been appointed Professor of Botany in the University of Edinburgh. His father occupied the same chair from 1845 to 1878.

—At the 32d annual commencement of the Philadelphia College of Dental Surgery March 1, 1888, the degree of Doctor of Dental Surgery was conferred on 58 graduates.

—On December 31, there were 1,200 persons in the Philadelphia Hospital, who required medical or surgical treatment. At the same date there were 164 persons in the Pennsylvania Hospital.

—At the invitation of Dr. Thomas Wistar a reception was given at the rooms of the Penn Club, March 8, to the Board of Managers of the Philadelphia Dispensary. A number of eminent physicians either are or have been connected with this dispensary.

—Dr. W. A. Swiers, who was graduated at the Jefferson Medical College in 1883, was convicted of abortion at Brookville, Pa., on February 14, 1888, and was sentenced to pay a fine and undergo an imprisonment of five years and three months.

—A raid, says the *Lancet*, March 3, 1888, has been made on a number of persons in Frankfort who have been describing themselves as dentists and American dentists without any legal right to do so. They have been obliged by the police to take down their sign-boards.

—Dr. E. B. Halliday, alias Stevens, who says he is a graduate of the University of Vermont, was arrested February 22, in Philadelphia, on the charge of forgery. The police authorities say that Halliday left the city in 1886, after obtaining the money on a check for $300, purporting to be from Bullock & Crenshaw, and only returned several days ago.

HUMOR.

GENTLEMAN (to consumptive friend)—"You walk very slow, Sam." Sam—"Yes, but I'm going very fast."—*Tid-Bits*.

TALMAGE ADVERTISES for a text for his sermon before the dental convention. How about "The noise of the grinders is low?"

MRS. VERBOSE: I dread typhoid more than any disease I know of.

Mr. Verbose: Typhoid! You surprise me! I should think lock-jaw would be your *bête noir*.

MAMMA—"Look Cissy, here comes the doctor! What a favorite he is. See, even the little chickens run to meet him." Cissy—"Yes, ma, and the little ducks cry 'quack, quack!'"—*Medical Herald*, Feb. 1888.

A NEW YORK DOCTOR claims that it is not a physical necessity that men should die. It is a bad habit that men have got into, however, and a very hard one to overcome, especially when they are so ably assisted by the doctors.

AN AWFUL BLUNDER.—Druggist (in alarm)—"James, run to Mrs. Smith's at once; I've made an awful mistake!" James (seizing his hat)—"Morphine—quinine—arsenic—poison——" Druggist—"No, no; she sent for ten cents' worth of one-cent stamps, and I sent her ten twos!"—*The Sun*.

JOE—"How did young Jones happen to get shot?"

Eli—"You see, he held a penny between his fingers for one of those western fellows to shoot at—"

Joe—"And he got his hand shot off?"

Eli—"No; he got hit in the left foot."

THE FOLLOWING was recently turned in as a bona fide composition by an Indiana schoolboy: "The human body is made up of the head, the thorax and the abdomen. The head contains the brains, when there is any. The thorax contains the heart lungs and diafram. The abdomen contains the bowels of which there are five, A, E, I, O, U, and sometimes W and Y."

THE SHERIFF at Mobile, Ala., resorted to rather novel means to overpower a rebellious prisoner. Armed with a dirk, the belligerent defied the prison officials to remove him to the dark cell, whereupon a neighboring fire company was ordered to turn a stream upon him. While he was vainly attempting to dodge the ice cold water the officials rushed upon and overpowered him.

ANXIOUS FRIEND: "My dear fellow, what are you doing at an open window with your coat off in such bitter weather? You will certainly be sick!"

Reckless friend: "I hope I will; my landlord is a doctor, and if I don't give him something to do he'll put my rent up!"—*Fliegende Blätter.*

PRACTICAL DARWINISM.—A Paris physician, says the Paris correspondent of the *Chemist and Druggist*, February 4, 1888, asked for permission to try a new treatment for consumption on the monkeys kept in the Jardin d'Acclimation. The establishment has many such inmates suffering from phthisis, as is the case with most monkeys brought to Europe, and the doctor thought he could cure them. Although he assured the director that his treatment was perfectly harmless, the permission was refused. Some of the physician's *confrères* say the reason of the denial is probably because the medicines had not previously been tried on the monkeys' more common and less valuable brothers, namely, men.

WHAT AILED SMITH.—A plainly dressed man, who introduced himself as Mr. John Smith, walked into a doctor's office, and having explained his symptoms, asked the doctor how long it would take to cure him. The doctor, who had treated the visitor with every possible courtesy, replied: "You will require several years' careful treatment under my personal supervision before you are perfectly well; but I think, Mr. Smith, that you will be able to resume your labors in the bank in about two months." "Doctor, you are fooling yourself; I am not Smith the banker, but Smith the street-car driver." "Is that so. Well, my good fellow, I don't see what you came to me for. There is nothing the matter with you except that you are not a banker."—*Texas Siftings.*

OBITUARY.

S. A. FOSS, M.D.

Dr. S. A. Foss died near Pleasure Ridge Park, Kentucky, Feb. 15, in the 67th year of his age. He was graduated at the Medical Department of the University of Buffalo in 1847.

THOMAS F. AZPELL, M.D.

Dr. Thomas F. Azpell, of the United States Army, senior captain in the service, died at Fort Lee on March 12. Dr. Azpell was born in the city of Philadelphia, and was graduated at Jefferson Medical College in 1849. He practiced his profession in Philadelphia until the breaking out of the Rebellion, and was said to be the first volunteer surgeon mustered into the service. After the three months' campaign he was transferred to the regular army, and subsequently rendered efficient service in the West. At the close of the war he was assigned to duty in the Shasta Valley, and remained in active service until his retirement, three years ago. His illness was very brief, as his health had been impaired by injuries which he received in the Modoc war.

THOMAS DELANO SWIFT, M.D.

Dr. Thomas D. Swift died in New York, March 3, in the 35th year of his age. He was graduated from the College of Physicians and Surgeons, New York, in 1879.

BYRON W. CHEEVER, M.D.

Professor Byron W. Cheever, A.M., M.D., Professor Metallurgy in the University of Michigan, died at Ann Arbor, March 6. He was graduated from the Medical Department of the University of Michigan in 1867.

Official list of changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from March 11, 1888, to March 17, 1888:

Major G. M. Sternberg, Surgeon, ordered to proceed to Brunswick, Ga., on official business, and upon completion of same will return to his proper station. S. O. 57, A. G. O., March 10, 1888.

First Lieutenant William D. Crosby, Assistant Surgeon, granted leave of absence for two months, with permission to apply for an extension of one month, to take effect after being ordered to a new station. S. O. 60, A. G. O., March 14, 1888.

First Lieutenant Jefferson R. Kean, Assistant, Surgeon, relieved from duty at Fort Sill, Ind. Ter., and ordered for duty at Fort Robinson, Neb. S. O. 56, A. G. O., March 9, 1888.

Changes in the Medical Corps of the Navy, for the week ending March 17, 1888:

Passed Assistant Surgeon W. H. Rush, detached from Navy Yard, New York, and to Naval Hospital, Philadelphia, Pa.

Passed Assistant Surgeon, J. M. Steele, detached from Naval Hospital, Philadelphia, and to Coast Survey Steamer "Bache."

Medical Inspector A. S. Oberly, detached from Navy Yard, Portsmouth, N. H., and wait orders.

Surgeon, F. L. Du Bois, ordered to the Navy Yard, Portsmouth, N. H.

Assistant Surgeon, James Keeny, ordered to the Receiving Ship "Minnesota."

Passed Assistant Surgeon C. W. Deane, detached from Marine Rendezvous, San Francisco, and to Coast Survey Steamer "McArthur."

Assistant Surgeon, E. W. Auzal, detached from Coast Survey Steamer "McArthur," and to Marine Rendezvous, San Francisco.

Passed Assistant Surgeon Clement Biddle, ordered to Naval Academy, Annapolis, Md.

WHOLE No. 1622.] MARCH 31, 1888. [VOL. LVIII., No. 13.

THE DISEASES OF THE STOMACH, AS JUDGED BY A NEW CHEMICAL REAGENT.[1]

BY PROFESSOR GERMAIN SÉE,
MEMBER OF THE FACULTY OF MEDICINE, PHYSICIAN TO THE HOTEL DIEU, PARIS, FRANCE.

[Professor Sée, having alluded to the difficulty of diagnosis of chronic affections of the stomach by the ordinary methods, and the unsatisfactory nature of some of the tests of the acidity of gastric juice employed, remarked that he had found Gunzburg's new reagent, the *phloroglucine vanillin test*, to perfectly meet the want of a delicate and sure test of the presence of hydrochloric acid in the gastric juice. He then spoke as follows.]

An important group of gastric diseases comprehends the cancers, the ulcers, the amyloid degenerations (which are rare), the scleroses or indurations of the sub-mucous tissue, the atrophies of the walls, and lastly, the lesions of toxic, and especially alcoholic origin. All that does not enter into this grave category has been classed under the name of dyspepsia. Formerly this term was applied to almost any gastric disorder—to gastralgia, to flatulence and even to vomiting, although the latter does not always imply a disturbance of the digestion. Dyspepsia was then merely a symptom-entity. Afterwards came Broussais with his famous doctrine of gastritis, which included a multitude of morbid conditions. This view, making dyspepsia an inflammatory trouble, was soon abandoned by reason of its absurd complications, and gave place to the *primordial dyspepsia* of Beau, a stupendous pathological bugbear, supposed to give rise to a variety of complaints—to chlorosis as well as anæmia, to tuberculosis and to cancer. This new notion soon came into discredit, and the German pathologists substituted for it that of mucous catarrh of the stomach—the word dyspepsia was erased from nosology. But the last word was not yet said. During the last eight years a vast amount of scientific investigation has been going on, which has put to the test accepted theories, and pretty effectually cleared up the mysteries connected with this subject. In my treatise on "Gastro-Intestinal Dyspepsias," (second edition, 1883), I have endeavored to demonstrate two facts:

1. That dyspepsia is always and necessarily a defective chemical process, due to some alteration of the elements of the gastric juice, and especially of the hydrochloric acid; the gastric juice may, moreover, be imperfect by reason of inertness of pepsin, or by reason of excess of peptones formed, or of mucus preformed, all of which retard the digestion. This constitutes dyspepsia proper. At the last three Congresses of German physicians, Van-der-Velden, Leube, Riegel, Ewald and Boas, Edinger and Jaworski, have endorsed, without giving me credit for my own researches and conclusions, this chemical view of dyspepsia, adopting principles of pathogenesis and a classification which I have long taught.

2. The second fact which I endeavored to bring prominently to light at the epoch when I published my book, was this: All the properties of the stomach which do not belong to the domain of chemistry, such as the sensory and motor innervation, are simply auxiliaries to true digestion; they may, in fact, undergo grave modifications without any real digestive trouble resulting.

[1] A paper read before the Academy of Medicine of Paris, January 17, 1888.

When the gastric innervation is impaired, there ensues a series of perturbations which often simulate the phenomena of dyspepsia, and to such an extent as to render the distinction very difficult; we have, however, to do in these cases only with nervo-motor states, with atony or spasm of the stomach.

Diagnosis of Chemical Dyspepsia.

Let us now inquire what are the chemical alterations which constitute true dyspepsia. First and foremost, we need to ascertain if the acids of the stomach, and especially hydrochloric, are deficient or lacking. To attain this end, and in order to obtain gastric juice, physiologists no longer rely on gastric fistulæ practiced on animals, or on accidental fistulæ, the results of wounds in man, for the subjects of these lesions always have the stomach exposed by an external opening, so that its condition has become in some sense pathological. Nothing can be considered as exact so long as the analyses do not pertain to the gastric secretion of a healthy man, or one with the stomach intact. Twenty years ago we used to employ Kussmaul's stomach-pump to obtain gastric juice; we now use a soft rubber tube, not much larger than a catheter, which is connected with an aspirator, and by this the juice is collected before and during digestion. Leube injects ice water before a meal, in order to provoke the gastric secretion, then extracts the gastric juice by means of the soft tube and aspirator. Jaworski and Gluzinski obtain the juice by a similar procedure, injecting water at 64.4° F., and aspirating the contents of the stomach after fifteen minutes. Ewald and Boas do not dilute the gastric liquid; they facilitate its extraction by means of pressures made over the abdominal and epigastric regions. I employ a similar method, as we really need but a few drachms of the gastric juice for purposes of testing. I make use of Potain's apparatus with pressure over the stomach; after a few short aspirations the liquid rises from the stomach into the receiving bottle, and is pure from any admixture with water. Durand-Fardel, my clinical chief, operates in a similar manner, obtaining by means of an incomplete vacuum the small quantity of pure gastric juice required, and without in any way injuring the stomach.

Reagents.

The reagents employed for investigation of the acids of the stomach are tropéoline, methyl violet, ferro-sulpho-cyanide of potassium, the phenic perchloride of iron, and the phloroglucine-vanillin test of Gunzburg; the Congo-red should also be mentioned.

1. Tropéoline, or Orange No. 4, first proposed by Van-der-Velden, is a concentrated aqueous yellowish solution, which becomes bright red under the influence of the least trace of acids. 2. Methyl violet was introduced by Laborde as a good test for lactic acid, which he considers the predominant acid in the stomach, being formed there, as well as hydrochloric acid. A few drops of this reagent, according to Laborde, gives with the contents of the stomach, if lactic acid be there, a pale blue, becoming deep blue. 3. If the acidity of the stomach be from the acids of fermentation (such as sarcolactic acid), it is best recognized by ferrosulpho-cyanide of potassium, which decolorizes the matters from the stomach. In a liquid form the stomach containing only two to four tenths per cent. of acids, especially of Hcl, the above reagents reveal the presence of the latter, while lactic acid only gives the coloration if in considerable quantity. In the latter case, as well as when the acidity is due to fatty acids (butyric acid, etc.), the best test is the phenic perchloride of iron, which gives an ash-gray color.

Now we know, according to the researches of Ewald and Boas, that during the first thirty minutes of digestion, lactic acid predominates, being formed prior to hydrochloric; then the two acids exist together (experiments of Berthelot and Richet); then there is a phase exclusively hydrochloric, which begins sometimes after half an hour, sometimes after an hour. This applies only to healthy states; in certain morbid states the digestive periods, and especially the lactic phase, are greatly prolonged. The existence of these phases, which I have called the *amylolytic period* and the *hydrochloric period*, brings confusion into our researches, for our reagents cannot enlighten us as to the relative proportion of mineral acids and organic acids. Here the recent discovery of Gunzburg comes to our help, his phloroglucine-vanillin test constituting the surest and most expeditious reagent. Gunzburg got the hint from Wiesner, who had observed that pine wood soaked in a solution of phloroglucine and moistened in strong hydrochloric acid, takes on a deep red color. Now the substance which with phloroglucine and Hcl gives the red stain, is vanillin. Two grammes (thirty grains) of phloroglucine, and one gramme (fifteen grains) of vanilline, with thirty grammes (nearly one oz.) of absolute alcohol, give a reddish yellow solution. One drop of this solution in presence of even a trace of a con-

centrated mineral acid, takes on immediately a bright red hue, while at the same time beautiful red crystals are deposited. The organic acids, as lactic and acetic, give only negative results in presence of this reagent. If the proportion of the mineral acid present is very minute, it will be necessary to slowly evaporate the liquid in a porcelain crucible; you will then get a deposit around the edges of fine red crystals. For this purpose you should use a spirit lamp, and take care that the liquid which you are testing does not boil. In testing gastric juice, you take a few drops of the fresh liquid from the stomach, filter, and add as much of the phloroglucine vanillin solution; evaporate with the precautions mentioned, and you will obtain the color reactions above described. When the gastric liquid contains considerable quantities of albuminates or peptones, the isolated crystals are not observed, but the bright coloring persists, and the crucible is covered with a mixture composed of albuminates and fragments of crystals.

[Prof. Sée further stated that this test is only of value as giving a proximate rather than an exact estimate of the proportion of hydrochloric acid in a given quantity of gastric juice. There are all shades of color, from faint to deep red, corresponding to a minus or plus quantity of Hcl in the gastric juice under examination. Moreover, the test is especially valuable in revealing the presence of mineral in contradistinction to organic acids. The professor then took up the subject of the time most appropriate for obtaining gastric juice. Leube extracts gastric juice seven hours after a hearty meal of soup, beef steak and bread; Riegel aspirates the gastric fluid five hours after a meal when the stomach is full. Professor Sée's method is as follows:]

"Instead of commencing the test at the end of fifteen minutes, and repeating it every quarter of an hour till four or five trials have been made (method of Jaworski and Gluzinski), a procedure which is very trying to the person under examination, I practice the extraction of the juice at the end of forty-five or sixty minutes after a meal; then, instead of administering ten ounces of liquid, I permit the ingestion of only a very small quantity of water, and in this way I am sure to obtain several drachms of gastric juice, which is quite sufficient for purposes of testing. I use now no other tests, repeating the examination the next day with Gunzburg's reagent, and perhaps the following day, till satisfied as to the acid quality of the gastric juice."

Application of the chemical data. Digestive troubles without chemical fault. —If now we apply these data to the divers diseases of the stomach, we shall see the pseudo-dyspepsias or nervous dyspepsias form a class apart from the chemical dyspepsias, properly so called. There are individuals who, with a normal proportion of Hcl in their gastric juice (0.15 to 0.2 per cent.), experience manifest digestive disorders—a sensation of pressure or of pain at the epigastrium, fulness after eating, gaseous eructations, capricious appetite, with absence of vomiting, regurgitations and emaciation. Chemical examination of the gastric juice shows, besides hydrochloric acid, lactic acid, sometimes in normal, sometimes in abnormal quantity. Digestion is especially painful after the ingestion of food of a heavy, "hearty" character; while light food, and especially amylaceous food, gives little trouble. These are "nervous dyspepsias," cases of atony of the stomach, or simply gastro-intestinal neuroses. Now for the positive data:

First Group. *Anachlorhydric secretions.* —A first group comprehends the anachlorhydric secretions; a second group, hydrochloric excess; a third group, the variations. From recent researches the fact is brought to light that the diminution or absence of the gastric secretion is not as frequent as was formerly taught. Thus, even in fever, true acid gastric juice is not completely wanting. In reality, we may reduce to two the morbid affections which are attended with a minimum of hydrochloric acid in the gastric juice: 1, carcinoma of the stomach, with or without dilatation, and perhaps atrophy or amyloid degeneration of the organ: 2, certain dyspepsias called mucous dyspepsias, and especially those which result from inanition, from marasmus, which constitute the most common kinds of dyspepsia.

Cancers.—[Prof. Sée remarked that all authorities of late years—Riegel, Van-der-Velden, Ewald, etc., have testified to the absence of Hcl in cancer of the stomach. Riegel attributes this to a specific and destructive action of the cancer juice, and to concomitant mucous catarrh. The same absence (which is not, however, absolute) has been noticed in amyloid degenerations and atrophies of the stomach, and in sclerosis.]

Mucous dyspepsias.—After carcinoma the morbid condition, which seems most to arrest the production of hydrochloric acid secretion, is mucous catarrh. It is certain that at the onset of the disease, hydrochloric acid is present; when later there are lesions of texture, as well as atrophy of the glands,

and interstitial deposits, the acid secretion is no longer capable of demonstration.

Dyspepsias from inanition and marasmus.—It is certain also that the production of Hcl may be wanting in all cases of marasmus, as well as after grave hemorrhages, etc. This absence has been repeatedly noticed in tuberculous, uræmic, and diabetic dyspepsias.

Second group. *Digestive troubles with hyper-secretion of gastric juice, or hyper-acidity.*—While gastric disorders with diminished or suppressed secretion are rarer than was once supposed, it has recently been shown by painstaking chemical researches that excess of hydrochloric acid secretion is one of the most common occurrences. In 200 cases of dyspepsia, Boas noted this hyper-secretion in 60. The dyspepsia from excess of acid is quite different from that in which acid is deficient. The distress is intimately connected with the act of digestion, and does not begin immediately after the introduction of food, but after the end of half an hour, an hour, or even later. What these patients principally complain of is the highly acid regurgitations of food, belchings of sour gas which comes up into the throat and mouth; there are, withal, burning sensations along the œsophagus, and severe pains, often of a piercing character, sometimes referred to the pit of the stomach. The appetite is feeble or *nil*, the tongue heavily coated, the bowels constipated, and in an advanced state of the disease, the patient is much emaciated. The analysis of the gastric secretions after a test meal, shows that this train of symptoms depends on excess of hydrochloric acid production; it is not even rare to note 0.4 to 0.5 per cent. of Hcl present. The organic and volatile acids are more or less completely wanting. In this kind of dyspepsia the digestion of proteinaceous matters is well accomplished; it is even probable, considering the rapidity of peptonization, that the presence of peptones in excess hinders the rest of the digestion. The digestion of starchy food is, however, impeded; for with more than one-tenth of one per cent. (0.1) of Hcl in the gastric juice, maltose ceases to be formed. If, in fact, we give to these patients an amylaceous mixture, and examine after an hour the filtered liquid from the stomach, we find plain evidence of *incomplete saccharification:* a solution of iodide reveals the presence of *erythro-dextrine*, while in the normal state we ought to find *achro-dextrine*, or even maltose.

Chlorhydric dyspepsia.—It is rare that the digestive disorders are any worse than those above described; but with excess of secretion the dyspepsia becomes *chlorhydric;* there is even sometimes a permanent hydrochloric-hypersecretion, so that in the morning when the stomach is empty, you will obtain by aspiration several drachms of liquid containing Hcl in abundance, and capable of digesting albumen. This form has been described by Reichman, Jaworski and Riegel, who found in four cases of this kind, a marked dilatation of the stomach, resulting, doubtless, from prolongation of the digestive process.

Résumé.—Without speaking of nervous dyspepsia, in which the gastric juice is normal, there exists a dyspepsia with deficiency of hydrochloric acid, and a dyspepsia with excess of hydrochloric acid; the latter may go on to constitute a *permanent hyper-acid dyspepsia.* But the etiological conditions of these acid dyspepsias are unknown; we know only that the dyspepsias characterized by excess of acidity are often associated with hæmatemesis, and consequently, with ulcer of the stomach. We know, moreover, that these dyspepsias oftentimes rest on a chlorotic basis; chlorotic patients are quite subject to attacks of cardialgia, which marvelously get well under alkalies given in enormous doses. A patient of this kind is now under treatment in Ward St. Jeanne, Hôtel Dieu.

Third Group. *Gastric juice secretions variable as to hydrochloric acid.*—This group includes dilatation of the stomach, of which so much has been said of late years. I am of opinion that this dilatation is not a primordial disease of the stomach, but only a symptom more or less pronounced of divers affections of the stomach, or, what is more frequently the case, of divers morbid states of the intestine. Moreover, the signs of gastro-ectasis are very uncertain, and in my experience are often referable to dilatation of the transverse colon. In doubtful cases, Ehrlich advises, in order to assure one's self that dilatation of the stomach exists, to give the patient salol in doses of fifteen or thirty grains. In the normal state this medicine passes intact from the stomach to the intestine, where it is mostly broken up by the pancreatic juice, then absorbed and eliminated at the end of an hour by the urine; if the salol does not appear till much later in the urine, it is because the stomach is dilated and retains the medicament. I have found four kinds of causes: 1. Fibrous or cancerous stenosis of the pylorus. 2. Atony of the gastric walls (through muscular enfeeblement). 3. Atony of the intestines, affecting the pylorus, and allowing gases to pass into and distend the stomach. 4. Intestinal

dyspepsia—simple chronic (mucous or membranous) entero-colitis, from which result gases by decomposition of the contents of the intestine, then pyloric insufficiency, and distention and dilatation of the stomach.

In five cases the gastric juice presented marked variations; in pyloric stenosis, there was no hydrochloric acid; in simple atony direct or consecutive, the acid was not lacking; less is known concerning the results of intestinal dyspepsia on the gastric juice. Out of thirty-three cases of dilatation studied by Riegel, twenty-one were simple; in none of these cases was the acid wanting, and in all the peptic force of the gastric juice was intact. Riegel has not made sufficient account of the influence of the intestine in producing dilatation. At any rate we may affirm that dilatation of the stomach is not destined to embrace or take the place of that dyspepsia which Beau considered the source of all evils; dyspepsia and dilatation are quite distinct, and dilatation may exist a long time without producing dyspeptic troubles. Nevertheless, in old dilatations, the gastric contents may undergo putrid changes, and thus a kind of "putrid dyspepsia" result.

Observations.—[Prof. Sée gives reports of sixteen cases in which examinations of the gastric juice were made. The first group comprehended cases in which Hcl was absent: *i.e.*, two of cancer of the stomach, two of tuberculosis (pulmonary phthisis), one of heart disease, one of diabetes, one of dyspepsia in an old paralytic patient, one of dilatation of the stomach of long standing, and one of gonorrhœal rheumatism. This group he calls the *anachlorhydric group*. The second group, which he calls the *hyperacid group*, comprehended one case of muco-albuminous enteritis of long standing, and another of dyspepsia from anæmia. The "normal group" contains two cases of simple dilatation with enteritis, one case of chronic gastro-ectasia without emaciation, and one of intestinal dyspepsia.]

Interpretation of the Anachlorhydric or Negative Digestions.

The fact that hydrochloric acid is wanting in the gastric secretion is no reason for the conclusion that the digestive process is a total failure. The stomach may lack the ability to do its work, and yet the intestinal digestion may be well performed, and the general nutritive functions may be still kept at the normal level. In cases of this kind, the stomach is only a place of transit for the food, and has no function but one of a motor kind,—"churning" and expelling the aliments; almost the entire amount of albuminates ingested escapes from the stomach before being peptonized, for the reason that no hydrochloric acid is secreted, and such gastric juice as the stomach produces acts only by virtue of the organic acids which it contains, and does not accomplish the peptonization of foods; the real labor of digestion devolves on the intestine.

A second cause favors the deterioration of the gastric juice, and the lessening or suspension of hydrochloric acid formation, namely, a vitiated state of the blood: the diabetic, the nephritic, the cardiac, the tuberculous dyspepsias are cases in point. Why these conditions interfere with the production of normal gastric juice is not well understood. At the same time, patients afflicted with these diatheses do not always suffer from indigestion; the intestinal digestion may be normal, and make up for the deficiency on the part of the stomach, and the general nutrition may be kept good. As soon, however, as uræmia or glycæmia, or venon stasis from cardiac failure or tuberculosis affects the intestine, diarrhœa, dependent on some one of those conditions, sets in, and sweeps off the products of digestion before their absorption; then the supplementary digestion having failed, malnutrition and emaciation rapidly follow.

There is a third class of cases, common enough in connection with anachlorhydric digestion. There are real gastric troubles—flatulence, slowness of digestion, pyrosis, pain and discomfort in the stomach, and nervous symptoms of a depressive kind. Hydrochloric acid is wanting, but the motor functions of the stomach are also at fault. The pancreatic and intestinal juices may even here compensate what is lacking on the part of the stomach, the liver may do its work well, and the patient may not seriously suffer from denutrition. In cancer of the stomach, all the functions of the stomach, chemical as well as nervo-motor, are compromised, while the production of the intestinal juices is suspended by the starving of the glands; the function of absorption by the lymphatics in both stomach and intestines is in abeyance, so that foods are neither transformed nor assimilated. On the other hand, in simple chlorhydric dyspepsia, the resources of the intestine suffice for the entire performance of digestion.

[Prof. Sée spoke of certain dyspepsias which are often misunderstood, and which are properly intestinal. The chemical functions of the small intestine may be disordered, or the large intestine may be in a

state of atony. There is pain at the pit of the stomach, and distention of the abdomen with gas, which sometimes forces the pylorus; the patient suffers from constipation, alternating with diarrhœa, cerebral and nervous troubles, severe dyspeptic discomfort three or four hours after a meal. The atony of the colon may result from simple "muscular debility," or a mechanical obstacle to the expulsion of the contents of the bowel, *e. g.*, tumors of the womb, or retroversion, hemorrhoids, hernia, etc.]

Bradypepsia.—There are cases which neither come under the category of chemical dyspepsia of the stomach, nor atony of the intestine, and which are characterized by simple retardation in the stomachal digestion; these are included under the head *bradypepsia.* We know, in fact, that the fragments of albumen in normal digestion appear, at the end of from thirty to sixty minutes, as if gnawed at their borders; we know that if the gastric juice is feebly acid, or neutral, or even alkaline (as is the case with the crustaceæ), the blocks of albumen remain unaltered till the moment when they pass the pylorus. This passage ordinarily takes place when the reaction of the gastric juice is at its maximum—then the larger part of the albuminous substances quit the stomach, and liquid extracted from the stomach at this time contains neither peptones nor acids.

But in the pathological stomach the time of expulsion of the morsels of albumen may vary from fractions of an hour to an entire night. In mucous dyspepsias, in dilatations of the stomach, there is a marked retardation. This slowness of the digestive act is not an indigestion, for the final result is good, and the food ends in being digested, peptonized and absorbed.

Treatment.—The common treatment of these gastric affections may be comprised under the three following heads: *Chlorhydrotherapy*, *Alkalinotherapy*, *Evacuants.* With regard to the administration of hydrochloric acid, I have always had grave doubts as to the utility of this medicament, despite the authority of Trousseau; certainly hydrochloric acid pure or associated with pepsin, cannot be regarded as indicated in the dyspepsias attended with hypersecretion of this acid, and these cases are very common. But it is necessary for one to be on his guard against mistaking for signs of acid dyspepsia, the patient's sensation of pyrosis, or of "burning gases," for in these cases the gastric juice may be neutral, or feebly acid. The only way to solve the question is by the stomach syphon; if hydrochloric acid is in abundance, the free administration of this acid can have only injurious results. We may go even further and say that when hydrochloric acid is wanting, or is present in very small proportion, as in cancer of the stomach, even here the administration of this acid medicinally does no good, for there is no formation of gastric juice, even in presence of the hydrochloric acid. Experience, moreover, proves its uselessness and, I may add, its danger.

The true province of chlorhydrotherapy is dyspepsia with deficiency of acid, or with predominance of the organic or volatile acids, and even in dilatation of the stomach with excess of organic acids. The dose in these cases would be twenty drops of the dilute acid in a little water, to be taken twice or three times a day during the course of the digestion, or after meals.

Alkalinotherapy.—This mode of treatment is still under discussion, at least, as far as the dosage is concerned. Generally, too small doses are given; what we want to do is to neutralize the excess of acid. To determine this excess of acid in a given case, you must aspirate a certain quantity of gastric juice after a test meal, and ascertain the quantity of Congo red necessary to neutralize the filtered gastric fluid. You add bicarbonate of soda till the Congo red turns feebly blue. A quantity in excess of the amount calculated should be used, as carbonate of sodium solutions are rapidly absorbed from the stomach. A proper prescription would be from one drachm to a drachm and a half of sodium bicarbonate dissolved in water, to be taken between meals, and continued for several days.

Evacuants.—These medicines are applicable to all cases of atonic affections of the stomach and intestine. If dilatation of the colon be the cause of the gastro-ectasis, *lavage* of the stomach is indicated as a therapeutic measure. If the intestine provokes pseudo-dyspeptic stomach symptoms, purgatives and laxatives are indicated. Purgatives have long had a reputation for being beneficial in gastric complaints. Why this is I know not, unless the dyspepsias under treatment were pseudo-dyspepsias, having their seat in the intestine.

Regimen.—Milk is prescribed at the present day everywhere (*urbi et orbe*), whether the practitioner have to do with an organic disease of the stomach, or a true gastric dyspepsia, a dilatation of the stomach, an atony of the intestine, or a muco-albuminous enteritis. In any and every one of these cases

you are almost sure to see the milk diet ordered, and often to the exclusion of all other treatment. [Professor Sée condemned this treatment as not giving the best results, and as being often irrational; the milk diet is good in diarrhœic complaints, and is the proper treatment—in fact a *sine qua non*—in ulcer of the stomach.

Another regimen commonly prescribed in dyspepsias, consists of light, tender, juicy meats, with little or no vegetables—starches and fats being forbidden. This regimen may lead to inanition, elements needed for nutrition being withheld. Such a diet has a temporary utility in patients whose gastric juice is poor in Hcl, *e.g.*, mucous dyspepsia, gastro-ectasis complicated with mucous dyspepsia.]

Amylaceous regimen.—In mucous dyspepsias and even in cancer where hydrochloric acid is totally lacking, it is useless and often dangerous to deprive the patient of food principles contained in the starches, and especially of such dietetic substances as are both amylaceous and nitrogenized. In conditions in which hydrochloric acid is in minimum proportion, the amylolitic period of digestion is predominant and rapid, and considerable absorbable maltose is formed with facility. In such cases soups with rice, etc., may be permitted, and also bread and biscuit; fat should be in sparing quantity, or withheld altogether; sometimes potatoes roasted in the ashes may be given, and pea soup or bean porridge.

Meat regimen.—A diet of starchy food ought to be rigorously interdicted in dyspepsias with hypersecretion of hydrochloric acid. Such articles of food are not transformed by the gastric juice; the excess of acid may determine spasm of the pylorus and retention of the amylaceous substances in the stomach, or exaggerated contractions of the muscles of the stomach, causing expulsion before the time, of the incompletely transformed or fermenting aliments. Fresh meat and fish are indicated in these cases, and the patient should virtually live on this diet—beef, mutton, fish, lean ham, in preference to fowl, game or veal. As for *beverages* in dyspepsias, those with hyperacidity are the worse for wine, and tea should be used instead. While fermented liquors are to be avoided, whiskey and brandy in moderation seem to do no harm, except to occasion a slight retardation of the digestion. [In dyspepsias with deficiency of gastric juice, on the other hand, wine is often an advantage by promoting an acid secretion.]

ON EXERCISE FOR THE PREVENTION AND CURE OF DEFORMITIES.

BY A. H. P. LEUF, M. D.,
OF THE UNIVERSITY OF PENNSYLVANIA,
PHILADELPHIA.

Its my object in this note to briefly call attention to what may be done by means of exercise for the prevention and cure of bodily deformities. Let me first say, however, that there is a difference between exercise and "athletics." The latter is a variety of the former. The one is usually either a sport or a business, and only sometimes an "exercise," while the other, if judicious, may be considered a therapeutic and prophylactic remedy of incalculable value. A wrong conclusion must be drawn if, in passing judgment upon the therapeutic value of exercise, our knowledge of its good effects is based only upon what little has been written on the subject. Too few of those qualified for the work have ever made it the object of their main efforts.

It is common enough to hear of the bad effects of over-exercise. Now is this not suggestive? Is not a remedy that is productive of evil also potent for good? If exercise, for instance, will cause an abnormal enlargement of the heart in health, is it not rational to assume that it will strengthen a heart that is abnormally weak? The heart is but a muscle, and what is true of other muscles in this regard is also true of it.

On *a priori* grounds, therefore, it would seem that exercise may be productive of good, especially when there is defective strength and muscle development. When we recollect that muscles never contract without acting upon other parts, we are compelled to admit that those other parts may also be influenced by exercise. For instance, increased muscular action causes increased heat production. It causes tension of the periosteum and bone to which the motive muscles are attached. Thus hyperæmia results, and bone growth is encouraged. Again it affects other structures, as for instance, the heart and lungs (circulation and respiration), by chest expansion, due to raising of the ribs when the proper muscles are contracted.

Deformities are treated by means of braces, supports and elastic bands—*artificial muscles*. These all weaken still more an already feeble muscle. How much better it would be to develop the weaker parts and so relieve the patient in a manner that is at once inexpensive, not unpleasant or ungainly, and that will insure a permanent cure.

But what has been done, and what can be done? is the important query. My experience with properly selected cases has been almost uniformly successful. Among them may be mentioned cases of spinal curvature, club-foot, malposition of parts (as for instance inversion of the toes), pigeon breast, flat chest, and others.

My opportunity for observation at the University of Pennsylvania is a great one, and it has been my good fortune to see young men and boys much benefitted by judicious exercise. Two cases of pigeon breast in boys under my care were much modified in less than three months by a judicious course of gymnastics. Mr. W. B. Page, at present a post-graduate student at the University of Pennsylvania, became the greatest high jumper the world has ever known, because he had *weak legs* in infancy and undertook to strengthen them by *exercise*.

In the summer of 1885, I had under treatment a young professional man much given to hard intellectual work, of sedentary habits, extreme disinclination for physical exercise, possessed of an ever-present feverish restlessness, and who was for years a sufferer from insomnia. His appetite, though for years voracious, gradually failed and left him a dyspeptic. He was tall, thin and flabby, had a weak heart and quick feeble pulse, often dicrotic in character. He was strongly urged to exercise in the open air. He impatiently gave it an unfair trial, consisting of over-exertions at irregular intervals. In the fall he developed a bronchitis that persisted despite the best treatment and a rest out of town and away from all care. In the latter part of February, 1886, he again took up his out-door exercise, and kept it up steadily with the result of getting into fine physical form at the end of the season, when he was wiry and minus fat, and when stripped reminded one of a race-horse. All his muscles were hard, his girths and weight had increased slightly; his mental and physical vigor had undergone a revolution; his appetite was very good and his insomnia gone. This is but one instance of a general restoration by suitable exercise of a worn-out body and mind.

A boy, 11 years of age, was brought to me in the summer of 1881, with posterior and left-lateral spinal curvature. He had had no appetite for about six weeks. He was pale and emaciated, having, according to my knowledge, greatly fallen off in those few weeks. His forward stoop and inclination to the right had been noticed for some time, but its onset had been so insidious that neither patient nor parents could fix a time for its beginning. He looked cachectic and had a family history of tuberculosis on both sides. He had been to school since six years of age, and was remarkably bright, advancing rapidly in all his studies, and was the pride of all his teachers. The treatment of this boy consisted in the internal administration of the syrup of the iodide of iron in half drachm doses t. i. d., and suitable exercises. A plaster jacket was not applied because of the fear that it might prove so oppressive in the hot weather as to debilitate him still more. The exercises consisted in hanging from a horizontal bar by both hands many times a day, at first for about a few seconds, the time being lengthened as the strength increased. During the intervals he spent most of the time at full length and on the flat of his back on a hard lounge with his hands and arms extended over his head. He was dieted so as to conserve as far as possible his nervous and digestive energies. In less than two months he was practically well, had a good appetite, ruddy cheeks, bright eyes, a somewhat rounded outline, and a *straight* column. The exercise was continued, however, for months afterward.

In the middle of October, 1887, I was consulted about a bright and healthy boy a little over two years old. He turned both toes in while walking or standing. Two or three physicians had been consulted, and one orthopædic surgeon, with the same result, which consisted in the advice to have braces applied to force the feet into proper position. This the parents were loth to do and asked me to suggest some other means worthy of trial. The boy required absolutely no general treatment whatever, for his health was perfect. I advised three exercises. One was to stand upright with the inner side of the shoes touching from heel to toe; then, while the heels remained in contact, the toes were to be turned out as far as possible, held there for a moment, and then returned. This was to be repeated *ad libitum* as an *amusement*. The second consisted in standing with the outer side of one foot against the wall and pressing the side and end of the foot forcibly against the wall. The third consisted in lying upon the floor at full length, back down, and everting both feet to the utmost extent, attempts being made to as nearly as possible touch the floor with the outer side of each foot. The object was in all these movements to exercise and develop the out-rotators of the lower extremity, *i.e.*, pyriformis, gemelli, obturators, and quadratus femoris. The result was excellent, for at

this time his feet diverge in walking and standing at about a right angle from each other, or as near that as is normal. This he was able to do perfectly within less than ten weeks after commencing the exercises.

Club-foot is often due to muscular weakness, and is generally treated with appliances, which instead of over-coming this defect too often increase it, either by doing the work of the muscles (as in the case of elastic bands), or by restraining them from action. I do not wish to be understood as saying that braces should be discarded, nor do I at all expect to see exercise altogether replace the brace, but I do hold that many cases now treated with mechanical appliances would be sooner and more permanently cured by means of proper exercise, and that those which require mechanical support would be discharged sooner from the surgeon's care if with the orthopædic apparatus there were prescribed strengthening exercises. This would vary with the kind of club-foot, and the condition of the muscles involved.

Knock-knee and bow-legs, due to feeble muscles, could also be most effectively overcome with judicious exercise. A good exercise for the treatment of knock-knee, due wholly or in part to weak muscles, would strengthen the adductors and the sartorius, gracilis, semitendinosus and semimembranosus, or inner hamstring muscles, which latter tend to adduct the leg at the knee. Besides this, there would be added growth and consequent strengthening of the internal lateral ligament of the knee from repeated tension. A good motion without the use of the pulley-weight is to stand with the knees together, and then abduct the thighs as far as possible, while the knees are flexed just enough to permit the exercise. The movement is facilitated by placing the hands on the inner side of the thighs and pressing outwards.

For bow-legs the proper motion is the opposite of that just described and brings into play the three glutei, vastus externus, rectus femoris, and tensor vaginæ femoris. Another good exercise is the reverse of that for knock-knee, and consists in standing with the feet apart and the hands upon the outer side of the thighs; the thighs are then approximated, while the knee is bent just enough to admit of the movement, and pressure is made upon the outer side of the thigh with the hands. This calls into action the adductors and inrotators of the thigh.

Round-shoulder may be real or apparent. When apparent, it is due to a forward inclination of the head and neck; and this is best remedied by several daily exercises at retraction of the head. Better still is a head-band connected with a pulley-weight. The band is fastened to the head while facing the machine, and the weight is raised by a backward movement of the head. This is repeated with a light weight until it becomes a little difficult, at which period all further efforts must cease.

The genuine round-shoulder is treated by repeated retraction of the shoulders while the hands are clasped behind the back. Strong efforts should be made to touch the scapulæ.

The literature upon this subject is meagre or plentiful as one happens to be choice or not in the selection of what possesses real merit. As a rule, however, this work has been left to the non-medical, and hence their writings are full of errors and absurdities. All works, however, contain much information that is of value. It will be my aim in further notes to call attention in detail to the treatment of special deformities. At present it is hoped that these general indications will be of use to the general practitioner and interest the specialist.

ANTISEPTIC MIDWIFERY, AS PRACTICED IN THE PHILADELPHIA LYING-IN CHARITY.

BY CHARLES P. NOBLE, M.D.,
SENIOR ASSISTANT PHYSICIAN.

The principle that all infection comes from without is now generally recognized, and antiseptic measures are used in practice for the purpose of preventing infectious material gaining access to the genital passages of the parturient woman. The theory that lying-in women are at times infected by way of the respiratory passages, though supported by some eminent authorities, can hardly be considered as proved. Infection from the bowel caused by abrasion with the dirty nozzle of a syringe has been reported. This method of infection must be exceedingly uncommon. Gonorrhœa existing as a vaginitis before labor, may subsequently extend through the uterus and tubes, and set up purulent peritonitis. Likewise pus from existing pyo-salpinx (or other pus sac) may gain entrance to, and infect the peritoneum during or subsequent to labor. Instances of both these events has occurred in the practice of the Charity. But here also the infection originally came from without. Hence in the healthy parturient woman the problem is to prevent the access of noxious matter to the genital passages. In carrying out the antiseptic practice here, it is especially borne in

mind that infection is usually carried by means of the fingers, instrument or other solid bodies brought in contact with the genitalia rather than through the atmosphere.

Whether we reject the respiratory passages as a route for infection, or not, it is unquestionably a fact that a prolonged residence at a hospital except under very exceptional hygienic conditions, deteriorates the health. Hence, patients are admitted only shortly before their expected confinement. While waiting they are ordered baths, not only for cleanliness sake, but to keep the skin active. A bath is given at the beginning of labor, unless there be some contra-indication. The clothing is also changed at this time. Whenever practicable the parturient is confined in a room separate from other patients. Thus her immediate environment is aseptic.

The nurse is impressed with the principles already noticed. She is directed that not only her hands but that all instruments and implements must be made aseptic before being brought in contact with the patients genitals. The solutions used to accomplish this, *after* the use of soap and water, are bichloride of mercury solution 1–2000 where practicable, or carbolic acid 2½ to 5 per cent.—this being used more especially for instruments. Where metal catheters are re-used they are to be passed through a flame, cleansed and washed in carbolic solution. Each patient has a separate syringe, the nozzles of which are to be cleansed and disinfected after use, and again disinfected before re-use. Antiseptic gauze is used for wash-rags.

The attendant is to bear in mind that in normal labor the less the genitals are disturbed the better. Hence, information gained by abdominal palpation, both as to the position of the fœtus and the progress of labor, is doubly valuable, since it is gained without risk. Before making touch the hands are scrubbed with soap and water, nor is the nail brush spared. They are then rinsed in the bichloride solution. Carbolized oil is used as an unguent. (This is not beyond criticism.) Touch is made as seldom as possible. The placenta is expressed. This may be regarded an antiseptic measure, since it tends to prevent the retention of clots in the uterus—a favorable nidus for germs. Rents of the perinæum, unless slight, are sutured; an open avenue for infection is closed. Slight rents are touched with carbolic acid. Soiled clothing is then removed, the external genitals and surrounding parts washed with bichloride solution; a sublimate gauze napkin and the binder are now applied. The sublimate gauze napkin is dampened in the solution where it covers the vulva. In instrumental labors, where the forceps have been used in the pelvic cavity or outlet, a sublimate vaginal injection, 1–2000, is given. When the uterine cavity has been invaded by the hand or instrument, it is also irrigated, and an iodoform pencil (100 grs.) is left in the cavity. This is also done after the delivery of a macerated fœtus. Care is taken that sublimate solution is not retained either within the uterus or vagina. The amount of iodoform seems large, but poisoning has not been observed. The formula for the pencil is:

℞	Iodiformi,	ʒ v
	Acaciæ,	
	Amyli,	
	Glycerini,	āā ʒ ss
	M. ft. bacilli, No.,	iij

The pencil dissolves slowly, and thus the genital passage is bathed in iodoform for about three days.

The after-treatment is based upon the principle that the puerperal state and puerperal processes are physiological. The vagina and uterine cavity are let rigidly alone, unless special indications arise. Sutures are usually removed on the eighth day. The patient's genitalia are bathed four times daily with the sublimate solution, and the gauze napkin changed when soiled.

The gauze is made in the institution by boiling cheese cloth in a carbonate of sodium solution to remove the oil, and, after drying, soaking it in the sublimute solution, and again drying.

This method of antisepsis has the double advantage of securing for the puerpera that repose which is so necessary for her well-being, and of protecting her against the risks of sepsis. At the same time, she is not subjected to the danger of sublimate and carbolic poisoning, from which she can never be entirely free when these agents are frequently used within the genital passages.

—The *Lancet*, Feb. 25, 1888, states that a medical missionary nearly lost his life through an outburst of fanaticism at Foochow, China. It seems that the doctor, who was attending a patient with hemorrhage, immediately proceeded to check the latter in disregard of a native superstition according to which delay should have been made until the patient's friends had finished consulting the gods in the joss-house. The patient died, and the Chinese would have boiled the doctor in oil but for the courage of some of the converts.

ASCLEPIAS SYRIACA (MILKWEED) FOR LUMBAGO.

BY B. F. RECORDS, M.D.,
SMITHVILLE, MISSOURI.

Dr. Clarence G. Hollister, in the REPORTER Feb. 18, 1888, gives an excellent article on this common and inconvenient affection. As to its pathology I have no comments to make. I have observed that it is more frequent in winter and spring than at other seasons, and in wet, damp cloudy weather than during dry, cold or bracing weather. It seems to be a result frequently of "catching cold." I have further noticed that there is tonic spasm of the lumbar muscles. A few years ago I was enabled to detect a malingerer who was anxious to have his trial for attempted murder postponed, claiming that he was suffering with lumbago to such an extent that he could not leave his bed. By order of the Court I examined him and found the lumbar muscles relaxed, and deolared him a malingerer, and in four hours after having been carried into the court-house, he walked off as vigorously as an athlete, and succeeded in making his escape. I have never used the combination of remedies mentioned by Dr. Hollister; though I believe it to be good, perhaps specific; yet I have a remedy that never failed me since I began using it in 1873, and that is a decoction of *Asclepias Syriaca,* or "silkweed," "milkweed," as it is called. It is indigenous in Western Missouri, and very generally, I believe, in the Middle and Western States. It grows on rich land, in fence-corners, meadows and cleared lands not used as pastures. It is perennial; grows rapidly from early spring until August, when it is from three to six feet high. It has a purple stock as thick as a leadpencil or even the size of an index finger. It has thick fleshy leaves, very brittle, and exuding a thick, gummy, milky juice; it generally has many branches at top; blooms in August; flowers in bunches, and is purple in color; bears a rough pod as long as a finger, and from half an inch to an inch in diameter at base, tapering to a point thorn-shaped, filled with a white, fibrous, silky furze, in which are the seeds. The root grows perpendicularly, a foot to eighteen inches in length, almost without rootlets, is white and tough; the root is the part used, and may be dug any time from August until April. Its physiological action seems to be diuretic, and mildly laxative. It increases digestion, and stimulates the appetite. That is as far as I have observed its action. I believe it is to some extent a heart tonic, though of that I am not positive as yet.

In 1873, I had a severe lumbago, for which I had tried various remedies, both internal and local, including electricity; but without relief. An old farmer said he could cure me, and related his own experience, and furnished the roots. I began using a decoction, drinking a half teacupful four or five times daily, and in a few days was completely relieved. Then I recommended it to all my patrons who called for treatment, and heard from them the most extravagant praises of its virtures, in return for my suggestions. Amongst my first cases was a man about fifty-eight years old, a painter, who had been disabled from work for nearly a month. He said that when he attempted to arise of mornings that he had to roll out of bed on to the floor, and hold to the bed-post with one hand, while attempting to pull on his pantaloons with the other. He could not stand still, but had to keep moving constantly until he could get to a seat. I gave him some of the roots, and he used the tea through the day and next morning, got out of bed and dressed with but little pain, and in a week was able to resume his trade. Since then I have met and treated perhaps a hundred cases with like results.

In 1875 or 1876, I saw an article in the MEDICAL AND SURGICAL REPORTER, from some physician in New York (his name and location I have forgotten), stating the action of *asclepias syriaca* in dropsy. At that time I had a typical case of general anasarca, in a man sixty-five years old. He had heart disease badly. His case grew from bad to worse, baffling me with the best remedies I could find. The anasarca had extended up to the thorax. He could not lie down. His body and limbs were distended until the skin seemed ready to burst. I regarded his case hopeless; but concluded to give the silkweed a trial. I punctured his limbs in numerous places and wrapped them in cloths, and thus started a flow of the water. I put him on a free use of the tea, and in ten days he was reduced to a mere skeleton; but could lie down and sleep comfortably. His appetite returned; his bowels from being torpid, acted normally, and there was a constant healthy action of the kidneys. His heart's action became more regular and its impulse strong. He lived a year and a half happy and content, when his heart suddenly failed, and he died in a few hours. I have used the same remedy in a few similar cases since and it has proved the *best* of all remedies so far.

Reports of Clinics.

CHARCOT ON APHASIA AND AGRAPHIA.[1]

REPORTED BY PIERRE MARIE.

In a lecture delivered at the Salpêtrière, in December, 1887, Professor Charcot showed a new case of agraphia and entered into some details of the history of this special mode of aphasia, to the study of which he has so largely contributed. I have thought it would be interesting to reproduce the principal points of the teaching of our master upon this subject. The patient was a woman, 64 years of age, presenting certain hereditary antecedents, who, in 1868, at the age of 44, had her first attack of hemiplegia. It was a right-sided hemiplegia and was accompanied by paralysis of the tongue. Normal speech, as well as movement, returned after the lapse of a certain time. But since this time there has existed a genuine impossibility to write, although the patient was perfectly able to hold the pen, knew what she wished to write, and had even preserved the accurate visual conception of the orthography of the words; but the idea of the letters was not present, she could no longer remember what form to give the letters. It was, moreover, certain that, prior to this time, she had possessed a considerable degree of education, which was proved by the examination of her expense book kept up to the date of her illness. It was also shown that, since the hemiplegic attack, the patient had read the newspaper daily and spoken distinctly. In 1879 there was a second attack, the woman falling suddenly in the street, stricken with left hemiplegia and complete loss of language. Since this time there has been a paresis of the right side, but language returned at the end of two years. In 1885 there was a third attack, followed by a certain difficulty of speech, characterized as a transitory trouble of articulation. Lastly, during the same year there was a fourth attack, resulting in complete and permanent loss of speech. Since then there has been a pseudo-bulbar labio-glosso-pharyngo-laryngeal paralysis, so extreme that sometimes it has been necessary, so difficult was deglutition, to nourish the patient by means of œsophageal tube. The laryngoscope clearly shows that the cartilages of the glottis cannot be sufficiently approximated to produce sound. But this is a phenomenon added to and wholly independent of the agraphia which has existed alone since 1868. Besides this, as is easily seen, the patient is neither deaf, nor verbally blind; she sketches, without hesitation, the objects of which the names are written or spoken. The inability to write does not proceed from paresis of the hands, which is not so great as to prevent her from holding a pen and copying fairly well the characters and figures printed or written before her. But when she wishes to "compose," to write what is dictated by her own thought or what is communicated to her, that is entirely a different affair, and she is absolutely incapable of doing it. In a word, this patient has preserved the visual image, the auditory image, and perhaps also the motor image of articulation, though of this last faculty one is unable to judge, because of the laryngeal paralysis. But she has completely lost the mechanism intermediating the translation of thought into written language. It is, therefore, a case of true agraphia.

According to the definition of Professor Charcot, agraphia is the more or less complete loss of coördinate movements communicated to the hand to express thought by writing, or more simply still, it may be called aphasia of the hand. This loss of coördinate movements is, moreover, independent of any other paralysis or paresis of movements, as may be proved by giving the patients characters or figures to copy, or having them execute such delicate work as sewing, crocheting, etc.

The word agraphia was introduced into scientific vocabulary in 1867 by the physiologist Ogle. The affection itself had already been exactly described by Marcé before the Biological Society, in 1856, who described the symptom of agraphia and sought to establish its independence. But this independence was not clearly and fully demonstrated until lately, and is due to the double series of proofs furnished by Charcot in 1883 and subsequent years. He first showed a case in which agraphia existed entirely disconnected from all other forms of aphasia, and, secondly, he proved that, in certain cases, the graphic faculty persisted, while other forms of language were wanting, and that in these cases the former may to a certain degree supplement the latter. It being thus shown that the faculty of written language may separately disappear or be preserved, its independent existence can no longer be doubted.

We thus clinically arrive at the isolation of four elements of speech: The auditory image, the visual image, the motor image of articulation, and the motor image of the

[1] Translated for the Reporter, from the *Progrès Médical.*

written word. In this connection M. Charcot noticed an interesting passage in the works of an English physician, Hartley (Observations on Man, 1749), a precursor of the great English physiological school of to-day, in which this physician by the simple methods of abstract reasoning reached the following conclusions:

"Words may be considered under four aspects: 1, as impressions made upon the ear; 2, as acts of the organ of speech; 3, as impressions made upon the eye by the written or printed character; 4, as acts of the hand in writing. Upon reflection we shall find that all the ideas excited by the word proceed from one of the four sources we have mentioned, especially from the first, or auditory element, and the third or visual element."

We thus see that in ascribing a preponderating importance to these two sources of the idea of the word, Hartley did not exclude the others. Such is the basis of the opinions of M. Charcot regarding the function of language, the multiplicity and relative independence of the sources whence we draw the elements of the word.

We thus find that the substance of the faculty of language may be resolved into four special modes of the memory of the word (or the impressions and acts by which we enter into relation with the same): suppress either of these partial memories and you produce one, and sometimes even several kinds of aphasia. According to the teaching of Professor Charcot, aphasia is only an amnesia; and, on the other hand, every verbal amnesia, however slight or limited, is an aphasia. Accordingly there will remain to be considered along with the corresponding aphasias, which represent the highest degree, also the auditory amnesias, the visual motor of articulation and the graphic motor, which represent a lower degree. Upon this point Charcot has always especially insisted, since, according to his belief, amnesia is the key of all the questions of the affections of language which we are studying.

This idea of memories and of partial amnesias having for its basis an independence of centres, is, as one may easily understand, the direct counterpart of the theory that seeks to establish an absolute supremacy of the sensory over the motor centres, and that the latter act only by a sort of reflex proceeding from the first. This theory is almost entirely rejected by Professor Charcot as being entirely too absolute. The notion of amnesia applied to each of these centres in particular, is, in fact, the counterpart of this theory, since it is based upon the independence of these centres among each other. Clinical facts, moreover, furnish us unanswerable arguments. Cases have often been found the most pronounced where verbal blindness was unaccompanied by any degree of agraphia; to such a degree, indeed (as Charcot has shown in several patients attacked with word-blindness), that in tracing characters with the hand, they come at last to understand the meaning of what they write. Likewise as regards verbal deafness, it is not rare to find it existing alone without aphemia. Several cases of this kind have been published, that of Hitzig being a beautiful example. We have here an evident proof that the motor centre of articulation has a distinct existence, and may be called into action without any reflex act from the auditory verbal centre.

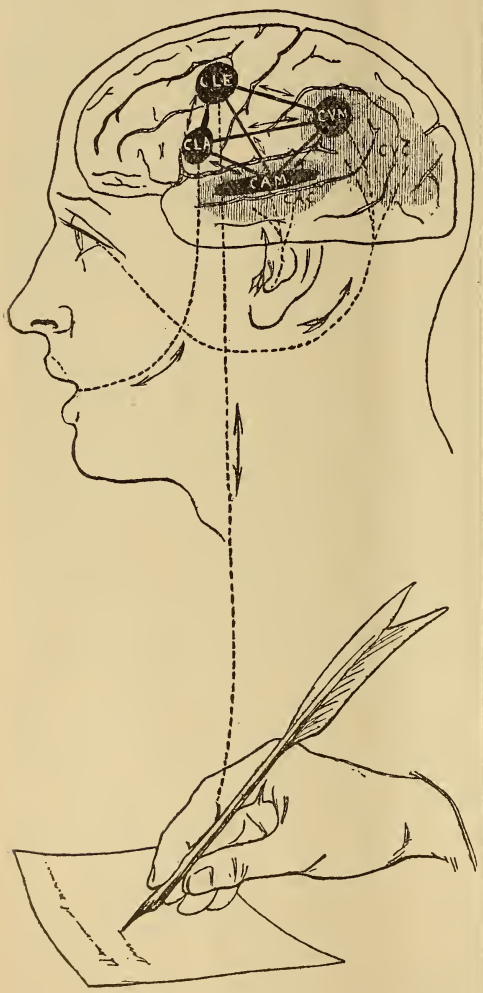
By the accompanying figure we may easily gain a notion of the centres of partial memory, the connections uniting them one to another, and of their relations with the external world. Let us take, for example, the centre for the memory of written language, or the visual centre of words, C V M; it is through the eye that the special ideas having the characteristics of the written word come to it, at the same time that the more general notions which concern, not the signification of the characters but simply their form, their external appearance, are being gathered in the common visual centre, C V C. If the visual centre for words be injured, the patient is still able to see the written words but does not comprehend them, he has verbal blindness. But if the lesion is not localized exactly at this point, which is generally the case, there is another phenomenon added: the patient will no longer perceive with this part of the brain, by the common visual centre for general visual impressions of objects—he will at the same time be attacked with both verbal blindness and with pschical blindness, the last appearing clinically under the form of hemianopsia.

The same may be said of the auditory centres, C A C, C A M.

As to the motor centres, whether of articulation or of writing, similar observations may be made, but with noteworthy differences. Just as we have seen the visual centre of words to be in intimate relation with the common visual centre, so the motor centre of written language, C L E, is in relation with the common motor centre of the superior member, and the motor centre of articulation, C L A, is in close connection

with the common motor centre of the tongue and lips. In order not to complicate the figure these two common motor centres have not been drawn, it being only necessary to mention this analogy.

It will be noticed that in the illustration the visual and auditory centres are related to



C V C—Common visual center.—C V M Visual center of words.

C A C—Common auditory center.—C A M Auditory center of words.

C L A—Motor center of articulate language.—C L E—Motor center of written language.

(The location of the centers is simply schematic and has no pretension to topographic or anatomical accuracy.)

the external world only by a single centripetal line. They are in reality only centres of impression. The motor centres of articulation and of writing are joined to the external world by a double line (or arrow): the one centrifugal, the other centripetal; that is to say, that while they are especially centres of expression, they are also, to a certain extent, centres of impression.

As to the lines uniting the four centres of the memory of words each to the other, they express the intimate and multiple connections existing between these different centres, and concerning the importance of which we shall speak later.

At present we wish to draw especial attention to the multiplicity and relative independence of the sources that furnish us with the elements of the word. Upon this notion, in reality, is founded the doctrine of functional supplementation put forth by M. Charcot in 1883, which is being more and more accepted. It is upon this conception that the method of re-education which has often produced such remarkable results, is based. A patient like Fraenkel's, attacked with verbal deafness, and not understanding the sense of spoken words, instinctively learns to reach their meaning by one of the following methods: he either repeats, articulates the words, and, by means of the movements, is finally able to understand them—in which case the motor centre presiding over the articulation of words comes to the aid of the auditory centre; or, again, the patient writes the words which he hears and in this way seizes their sense—in which case the motor graphic centre supplements the auditory centre. Frequently, also, as has been shown by several examples, the word-blind patient comes to understand the written words by retracing the characters either with the pen or with the finger in the air, in which case the graphic motor centre aids the visual centre. The stronger impressions furnished by the graphic motor centre are thus seen to re-inforce the weak impressions, and those of a doubtful character supplied by the visual impressions. We may thus see the visual centre supplied by the graphic centre, and the auditory centre by the motor centre of articulation; and this is because the memory of the movements of articulation, and the memory of graphic movements, in the same manner as visual and auditory images, form a part of interior language, and may either of them awaken the idea of the word.

But the law of the independence of centres is not an absolutely general law, since there are cases in which the suppression of sensory visual, and auditory centres, paralyzes the centre of articulation and produces motor aphasia or agraphia. According to M. Charcot the reason of these varieties is be-

cause the apparatus of language does not develop alike in all individuals. There exists in this respect very different aptitudes and types. These depend upon whether, in the interior language, this or that centre is predominant in the representation of the word, whether in this or that individual the formation of the idea of the word takes place preferably by one of the mechanisms set forth above; in which case we have to deal pre-eminently with a visual mechanism, an auditory, a graphic motor, a motor of articulation, or with either indifferently in the case of those who reach the representation of the word by either of the four methods in question. This idea of the different types of interior language was introduced into science by M. Charcot, and we insist upon it here because of its extreme importance. Without this it is impossible to clearly understand the faculty of language or the different varieties of aphasia. It should be clearly understood that these distinctions are not the classifications of a sterile scientific eclecticism, but are the exact expression of the living reality.

It is indeed sufficiently clear that among the physiologists and psychologists who have most carefully studied this question of the sources of interior language, and who have shown the most penetration in their investigations upon themselves, some are exceptional in auditory development, while in others the visual or the motor centres are pre-eminent. It is thus easy to understand, as M. G. Ballet has shown in his thesis, why their results differ so much, although in each particular case the author was wholly in the right.[1]

This conception of individual varieties also enables us to understand that among the indifferents, as they are called by Charcot, those whose centres enjoy the greatest autonomy, in the case of the destruction of one of these centres, there follows more easily the phenomena of substitution by the other centres. On the other hand, those who have cultivated only a single order of the memory of verbal images, find themselves entirely at a loss if the centre of that memory is interfered with. In such cases, for example, one may see a single lesion of the auditory centre lead also to a verbal deafness, or true motor aphasia, although the convolution of Broca may be the seat of no lesion whatever; or a limited lesion of the visual centre may produce agraphia without any lesion in the centre of Exner (base of the second left frontal).

We may thus see that all those cases which *a priori* might be considered as against the theory of the independence of the faculty of written language, are in reality explained in the most natural manner, and that agraphia, as M. Charcot has shown, none the less remains a form of a perfectly autonomous aphasia.

[1] One may, for example, say that in M. Stricker the motor centres are especially developed.

It is easy to understand in view of such extensive physiological variations how difficult it becomes to trace the characters that may be clinically distinguished in cortical aphasia (lesion of the centres themselves) as distinct from aphasias of conduction or subcortical aphasias (lesion of the fibres proceeding from these centres). It does not appear that up to the present time this subject has been studied with any accurate or practical result.

Special Correspondence.

CINCINNATI LETTER.

A most humiliating affair, not only to one of our most prominent medical men, but also to the profession of the city at large, has occurred recently. A doctor's wife was stricken with cancer. The growth was removed, and she was free from it for a number of months. The disease returned with marvellous activity. Everything that could be done was done by the best of the profession of this city and the East, but she went steadily and rapidly to the end. Every one else had given her up. A wife of only four years and the mother of three children, life was dear to her. The Faith cure was urged upon her, but her husband, of course, refused. Her friends and relatives began to talk, and it was whispered about that because she was married to a doctor she could not avail herself of all methods of cure, and must die for want of freedom in her selection. Under this fire what was left for the husband but to give up. Under his protest she went to the Faith doctors, and every day they told her she was getting better, while she was really growing steadily worse. Their encouragement possibly did her some good, but she died all the same, and let herself as well as her husband out of misery. This has been a most unfortunate occurrence, for the simple fact of the wife of a prominent physician going to these quacks, even though unassisted, will be a very great thing for them to talk about. Probably they would have cured her had they "seen her earlier," or perhaps "she had not enough faith."

This story reminds me of another quack in our midst—an old "Dutch woman," a so-called "Wasser Doctorin," who has proba-

bly the largest practice in the city, and who tells bold falsehoods fearlessly about the most prominent medical men in the city consulting her and offering fabulous sums for her cures.

An effort which commends itself to the very great majority of the profession of this city is being made to bring our two general medical societies together again. About fifteen years ago there was a quarrel and a split in the Cincinnati Academy of Medicine, and some of the disaffected members resigned and started what is known as the Cincinnati Medical Society. Since that time there have been two medical societies here—a very unnecessary and unfortunate condition of affairs. Though the Academy was much the larger, having three times as many members as the other, yet it was not representative of the whole medical profession of the city. In the fifteen years which have passed, some of the men who took part in the old quarrel have taken *le grand voyage;* others have found more important things to occupy their minds, and a class of younger men has grown up who know little of this old grudge and care less. These men, when the yeas and nays are called, control both societies. They are in favor of a combination, and it is to be hoped that they will succeed in effecting one. Negotiations are already in progress to this end.

The coming meeting of the American Medical Association in this city, May 8 to 11, promises to be one of much interest. Cincinnati is accessible for the East and the West, the North and the South, and a large turn-out is confidently expected. The local profession is working very harmoniously, and arrangements for the social and scientific entertainment of our visitors are progressing nicely. The Chairman of the Committee of Arrangements is Dr. W. W. Dawson, Third and Broadway.

At the recent annual election of officers for the Cincinnati Academy of Medicine, the following was the result: *President*, Dr. C. D. Palmer; *First Vice-President*, Dr. Wm. Judkins; *Second Vice-President*, Dr. J. C. Oliver; *Secretary*, Dr. G. A. Fackler; *Treasurer*, Dr. Geo. E. Jones.

The last month has been a busy one in the medical college circles of our city. Commencements, alumni meetings and banquets have engrossed the professional attention. Many hearts have been made happy by the winning of the coveted prize, and many others are equally joyful at getting the wished-for sheepskin. A few have been called to the green-room, and some, failing to pass this second ordeal, have gone home in disgrace.

The Cincinnati College Commencement was the first, with 12 graduates and an able address delivered by Dr. L. C. Carr, Professor of Obstetrics in that instituton. The exercises were held in College Hall.

The Commencement exercises of the Ohio College of Dental Surgery were held at College Hall on the evening of March 7. Prof. H. A. Smith, Dean of the Faculty, presided; the diplomas were conferred and an address made by Geo. W. Keely, D.D.S., of Oxford, Ohio, President of the Board of Trustees. Prizes were awarded by Prof. Smith, an address made by Rev. Dudley Rhodes, and the class oration by A. B. Fletcher. The prizes were distributed as follows: Gold medal for best general examination, to H. T. Smith, of Cincinnati; second prize for best operative work, a gold medal, to J. F. Hussey, Ohio; third prize, a gold medal, for best mechanical dentistry, to W. W. Wallace, Ohio; fourth prize, a free ticket to session, for best examination in the junior department, to R. R. Bronston, of Indiana. The graduates of the Dental College were 46 in number. After the exercises a banquet was enjoyed at the Burnet House.

The exercises of the Miami College Commencement took place at the Odeon the evening of March 10. Rev. Dr. E. D. Morris, of Lane Seminary, made the opening prayer, and Prof. W. H. Taylor, Dean of the Faculty, followed with an address, reviewing the work of the college for the past year.

Mr. A. H. McGuffey addressed the graduates and delivered the diplomas. He advised the class to hold fast to the dignity of the profession of which they were this night made members; to ever hold in reverence their *alma mater* and the gentlemen who had taught them there with such patience and thoroughness. The prize of Prof. Daniel Millikin, a handsome microscope for the best examination in chemistry, was awarded Mr. H. S. McVey, a junior; Prof. Langdon's prize, a case of surgical instruments, was given to Benjamin Neal for the best anatomical examination. The William's prize, for the best examination in ophthalmology, to E. R. Axtel. The faculty prize, one hundred dollars, was awarded L. S. Elrod. The valedictory address, on the part of the faculty, was delivered by Dr. E. S. Walker, Professor of Surgery, who took as his subject, "The Malingerer." He startled his audience in the beginning by telling them that there was probably not one among them who had not at some time or other been a malingerer, to

avoid the performance of some undesired task. He then went on to state the people who were most likely to be malingerers, the diseases most likely to be simulated, and those who made up the class of malingerers. The greatest number were soldiers or sailors, who wished to escape duty or danger; yet it was found among all classes and conditions, even among children. It called for the most careful judgment on the part of the physician or surgeon; for it was certainly better that twenty guilty men should escape than that one man who was really ill should be condemned as a malingerer. The speaker reported a number of cases, and gave some unique ways in which disease and injury had been feigned. He said it was often the case in hospitals that patients would wish to remain after they were entirely recovered, and would feign all sorts of imaginary ailments to attain this end. A mixture which usually fixed them up in a hurry was the "mistura diabolica." It is composed of asafetida, aloes, and valerian, and is a terrible compound.

Closing his remarks on malingering, the speaker then turned to the graduating class and gave them some good advice. As a good code of ethics, he recommended the golden rule, and he told his hearers not to be jealous overmuch of their neighbor's success and to mind their own affairs, with much other good counsel. After the commencement exercises the faculty entertained the graduating class, the alumni and the staff of the Cincinnati Hospital, at a sumptuous banquet at the Burnet House.

The following officers were chosen at the alumni meeting: *President*, Dr. Chapman; *First Vice-President*, Dr. F. W. Langdon; *Second Vice-President*, Dr. Collins; *Secretary*, Dr. J. C. Oliver; *Treasurer*, Dr. B. Merrill Ricketts; *Executive Committee*, Drs. Stanton, J. A. Thompson and G. R. Holmes.

The commencement of the Medical College of Ohio occurred at the Odeon, on the evening of March 8, 1888. It was the 69th annual commencement of this well-known college, and the spacious hall was crowded to its utmost capacity with the friends of the institution. The trustees of the college, the faculty and alumni occupied seats on the stage and formed a brilliant assemblage. Rev. W. H. Warren, pastor of the Vine St. Congregational church, opened the exercises of the evening with prayer. Prof. W. W. Seeley, Dean of the College then made a few remarks stating the work of the year, and referred to the loss of three of the candidates by death from typhoid fever. Several others were sick so long a time from this disease that they were deterred from coming up for examination. One of those who died was Dr. Anderson Rawlston, who would have graduated last year but remained over a year as interne in the Cincinnati Hospital. Here in the faithful discharge of duty he contracted typhoid fever, and after a long and terrible struggle gave up his life. By his geniality he had made for himself a host of friends while studying here.

Hon. W. W. Dickson, president of the Board of Trustees, with the usual assistance from Dr. Conner, delivered the diplomas to the happy graduates who numbered seventy in all. Mr. Dickson then made an address to the class of which the following is an abstract:

That you have chosen medicine for your profession, indicates that your aim is not simple money-getting. No doubt if you are reasonably successful you will make a living by your chosen life work, but were it your ambition to become a plutocrat you would scarcely have selected medicine as your route to riches. Yet money has its uses. A reasonable amount of it means good food, good clothing and shelter. More of it and we have the luxuries, a fine house, rich raiment and dainty food. And then with plutocratic wealth you may play polo, ride behind a $50,000 horse, sail the seas in costly yachts, cover your wife with resplendent clothing and diamonds, or she may follow a pug dog costing thousands. Money is an excellent servant but an ignoble and remorseless master. Young gentlemen, if you go from this hall determined to keep the better sentiments uppermost, if you reserve your homage for moral and mental worth, you may accomplish much. But we speak louder by deeds than words. So bear yourself in your profession that it will command respect.

The following prizes were then distributed: Prof. Whittaker's prize, a case of instruments of precision, for the best examination in theory and practice, given to Dr. Theodore Mumaugh, Lima, O.; Prof. C. D. Palmer's prize in obstetrics and gynæcology, case of instruments, for the best examination in this department, to Dr. John Edwin Wilson, Falmouth, Ky.; Prof. P. S. Conner's prize in surgery, a case of surgical instruments, to Dr. W. Edgar Hover, Lima, Ohio; Prof. W. W. Dawson's prize for best bandaging, to Dr. George A. Welch, Athens, Ohio; Prof. Dawson's prize, for best dissection, a gold medal, to Dr. Homer C. Bennett, of Bellefontaine, Ohio; Prof. Thad. A. Reamy's prize in clinical gynæcology, a gold medal, to Dr. Ed. W. Johnston, Union City, Ind.;

Drs. DeBeck and A. V. Phelps of the histological laboratory gave a prize, a cabinet of specimens, to Dr. Albert H. Freyberg, of Cincinnati, for the best examination in this branch; the Faculty prize, for the best examination in all branches, was given Dr. John B. Murphy, of Cincinnati; appointment as Resident Physicians to the Cincinnati Hospital, Drs. Thos. Hayes, S. F. Kramer and David Wolfstein, of Cincinnati; as Resident Physicians to the Good Samaritan Hospital, Drs. Otto Juettner, Cincinnati, and U. D. McDowell, Millersburg, Ohio; as Resident Physician to the Children's Hospital, Dr. George W. Davis, Batavia, Ohio; as Acting Assistant Surgeons to the National Military Home at Dayton, Ohio, Drs. Geo. H. Welch, Athens, Ohio, and Clarence M. Parkes, Sullivan, Ind.

Surgeon-General John A. Billings of the United States Army stationed at Washington, and a graduate of 1860, was then introduced, and delivered an address. He took for his subject the Medical College of Ohio before the war, and remarked that before he was through his paper he was not sure that he should not have called it The Medical College of Ohio during the war, for those days of early growth and progress were so replete with strife. He gave a most graphic description of the early days of the old College, and perfect pen pictures of some of the older members of the faculty about whom we now read. He related how it was the custom then to require of the candidate for graduation the writing of an inaugural thesis. It was the performance of this melancholy duty which led him into the line of work which has occupied the greater part of his time for the past twenty years. In the search through the public and private libraries of Cincinnati, Philadelphia, New York and elsewhere, which lasted over a period of six months, he became convinced of three things: The first was, that it requires a vast amount of time and labor to search through a thousand volumes of medical books and journals for items on a particular subject, and that the indices of such books and journals can not always be relied on for their contents. The second was, that there are in existence somewhere over 100,000 volumes of such medical books and journals, not counting re-prints. The third was, that while there was nowhere in the world a library that contained all these books there was not in the United States even a fairly good one. This it was that led him at the close of the war to try to establish for the use of physicians a fairly complete medical library at Washington, and in connection with this to prepare a comprehensive catalogue and index which would spare medical writers and teachers much drudgery. The paper was quite long, and full of interest.

The valedictory address, on the part of the Faculty, was made by Prof. C. D. Palmer. An elegant collation was served after the close of these exercises.

Periscope.

Allochiria.

At the meeting of the Biological Society of Paris, January 14, 1888, M. Gellé reported a case of auditory allochiria, and remarked that allochiria is the perception of sensation on the side of the body opposite to that which is irritated. This phenomenon has been especially observed since Obermeister's description, in patients suffering with locomotor ataxia and in affections of the cord, either traumatic or otherwise, and up to the present time, the observations have been with cutaneous sensations. The patient, feels, for example, in the right leg a blow struck upon the left leg. In Gellé's case, a noise produced at the right ear is heard only at the left. The patient is affected with Menière's vertigo, with manifest lesions of the middle ear, especially the left. Pressure upon the left ear provokes vertigo after a time, and causes pain; hearing is also painful on this side. The right ear is relatively good. The patient is not tabetic, nor paralytic, nor hysterical, and she has since recovered. The patient heard on the left side a piping sound produced in the right carotid. M. Féré stated that he had observed the same kind of phenomena in hysterical patients. Brown-Séquard thought that M. Gellé's observations tended to confirm the theory which he had maintained for a long time, that there do not exist double centres, but simple centres for the two halves of the body.—*Progrès Médical*, January 21, 1888.

Interstitial Salpingitis.

Dr. H. J. Boldt, in a paper on interstitial salpingitis in the *American Journal of Obstetrics*, February, 1888, says that the inflammatory processes occurring in the Fallopian tubes have usually been divided into catarrhal salpingitis and salpingitis. He adopts the term interstitial salpingitis from A. Martin's book, "Pathologie and Therapie der Frauenkrankheiten," because it expresses the pathological conditions present. He has not found primary tubal inflammation; for usually

the inflammation is transmitted from the uterus. Inflammation of the mucosa may be catarrhal or purulent, and varies greatly in degree. In interstitial inflammation the connective tissue between the muscle-bundles is first invaded, and the process varies from slight inflammation to partial destruction of the walls by suppuration. Boldt considers interstitial inflammation to be secondary to that of the mucosa, though in gonorrhœic and septic infection in the puerperal state the disease may run such a rapid course that both appear almost simultaneously. He considers that suppurative salpingitis is always caused by septic or gonorrhœal infection; also that it is possible for catarrhal salpingitis to be converted into the purulent form by intense irritation, as by intra-uterine injections, or incautious manual examinations.

Before subjecting patients with disease of the Fallopian tubes to operation, Boldt always treats them for a period varying from four months to one year, in order to satisfy himself that they cannot recover without operation. But for pyo-salpinx, following or accompanying the puerperal state, he advises immediate operation.

Four illustrative cases are reported in the paper referred to, and the conditions found under the microscope are described and figured. The first stage of the process is given as an œdema of the interstitial tissue; the next is marked by an infiltration with inflammatory corpuscles, with a simultaneous breaking up of the smooth muscle-fibre into such corpuscles, which are also derived in part from the connective tissue. The inflammation varies much in intensity, and may result in more or less breaking down of the tissue in the formation of miliary abscesses, or in diffuse purulent infiltration. Interstitial salpingitis is considered the initial form of both miliary and diffuse tuberculosis. Besides abscess and purulent infiltration, hyperplasia and atrophy are described as terminations of the process. Boldt thinks that in atrophy of the Fallopian tube a number of the epithelia and muscle-fibres perish by being converted into medullary or inflammatory corpuscles. Atresia of the tube is explained upon this hypothesis, or else that the epithelia have been destroyed by ulceration. In all cases of interstitial salpingitis described by Boldt, more or less marked peritonitis could be seen, either in the form of acute swelling or as pseudo-membranes, caused by the transportations of infectious material—micro-organism or ptomaines—to the peritoneum, by way of the connective tissue.

Treatment of Migraine with Antipyrin.

T. J. Bokenham, of St. Bartholomew's Hospital, in a communication to the *Practitioner*, February, 1888, says that during the last two months he has had an opportunity of treating as many as twenty-six cases of migraine with antipyrin. The results have been in every case perfectly satisfactory, although the dose given has been quite small, in no case exceeding four grains. He describes three typical cases: namely that of a near relative; that of a girl, the members of whose family exhibited epileptic tendencies; and an attack as occurring in himself.

His own migraine is usually brought on by over-use of the eyes, and is almost invariably preceded by well-marked teichopsia, which lasts for from half an hour to several hours. As the attack proceeds, he gets a tender spot on some part of the scalp, generally in the right parietal region, a vascular disturbance, with throbbing behind the right eye. The first time he took antipyrin it was in a dose of three grains, and after the pain was well developed. In a very short time the throbbing entirely ceased, leaving only a dull aching pain behind the eye; the flushing of the face also diminished. After half an hour he took a second dose of three grains, and by the end of an hour from the time of taking the first dose he was quite well, with the exception of a slight tenderness of the scalp. Since then he has tried the drug, in the same dose, taking it as soon as the teichopsia comes on, with complete success in altogether preventing the attack.

The second case is that of a woman who had been subject to attacks of migraine for many years. The starting point of her attacks is also in the eyes. For a long time large doses of ammonium bromide were successful in cutting short the attacks, but recently this drug seems to have lost most of its power. Antipyrin entirely relieved the prostration and pain after the second dose of three grains.

The third case is interesting in that it points to another class of cases in which antipyrin may be of use, namely epilepsy. Here the mother is epileptic, the father is of a very excitable temperament, and another member of the family showed signs of weak intellect. In this case migraine usually followed any undue fatigue, and was attended with a good deal of prostration. The author says he happened to be with her during one attack and promptly administered antipyrin. The headache yielded entirely after the second dose of four grains. He has also under observation two epileptics, in whom the fits are

preceeded by a well-marked aura in the shape of tingling of the extremities of the fingers. They are directed to take, as soon as they feel this sensation, ten grains of antipyrin in a little water. If the theory of Dr. Liveing concerning the close pathological relation between migraine and the other so-called paroxysmal neuroses be true, there is some hope that in both these diseases we may be able to check or to cut short the attack by the timely use of antipyrin. He has not yet had the opportunity of observing the effect on these two epileptics, but it would certainly seem to be worth a trial.

He feels sure that antipyrin requires only to be known to become a regular remedy in the treatment of migraine, and that practitioners will use the small dose with less hesitation than they would the large ones previously given.

Treatment of Inflammations in the Region of the Ileo-Cæcal Valve.

Dr. M. H. Richardson, surgeon to the Massachusetts General Hospital, in a paper read before the Suffolk District Medical Society (*Boston Med. and Surg. Journal*, January 26, 1888), sums up his conclusions as to the proper treatment for these cases in the following propositions:

1. In mild cases of inflammation in the region of the appendix there should be no surgical interference till physical examination reveals the presence of an abscess, which should be incised by the post-peritoneal method.

2. In violent cases, where it is evident that there is a general peritonitis, laparotomy should be done immediately, just as soon as a diagnosis of general peritonitis has been made.

3. In violent cases where it is doubtful whether the general peritoneal cavity has yet been invaded, and where the history and the physical examination favor the presence of an abscess in the ileo-cæcal region, though it is impossible to locate the exact seat of the inflammatory process, an exploratory incision should first be made in the right iliac fossa, and the ileo-cæcal region explored post-peritoneally.

4. The best incision to reach the appendix in the average case, is along the outer border of the rectus, about four and a half inches from the spine of the pubes.

5. The best incision for extra-peritoneal exploration is parallel and close to Poupart's ligament, beginning in about the centre, and extending outwards and backwards a sufficient distance.

At the same meeting Dr. J. W. Elliot reported a case of perforation of the vermiform appendix, causing an intra-peritoneal abscess and general adhesive peritonitis, and the following propositions were formulated for discussion:

1. For cases of chronic or subacute perityphlitis with a small tumor, or without tumor, expectant treatment.

2. For cases of chronic or subacute perityphlitis with a large and increasing tumor, extra-peritoneal incision.

3. For cases of acute perityphlitis with threatening symptoms and with tumor, extra-peritoneal incision.

4. For cases of rapidly acute perityphlitis with alarming symptoms, and without appreciable tumor, exploratory incision (extra or intra-peritoneal).

Dysentery in Ireland.

At a meeting of the Royal Academy of Medicine in Ireland, on January 13, 1888, Mr. Conolly Norman made a communication as to the cause of the outbreak of dysentery with which he had to deal in the Richmond Lunatic Asylum, in Dublin. Mr. Norman stated his belief that the outbreak was due to defective drainage, and laid down the following as probable general laws that regulate the appearance of dysentery: 1. Dysentery is communicated through exhalations from a soil saturated with the products of organic decomposition. 2. The incidence of dysentery at particular times and seasons is due to the increased moisture of the soil at such times. 3. When dysentery breaks out there is commonly a concurrent outbreak of severe diarrhœa. 4. Dysentery appears where dysentery has been before. 5. When dysentery appears over a large area, including its own haunt, it appears in the latter situation in its worst form and to the greatest extent. 6. Like other malarial affections, dysentery attacks by preference those who are not acclimatized to the conditions that have produced it.

Mr. Frazer believed that dysentery was and could be contagious, for he remembered making a *post-mortem* examination in the Richmond Hospital from which he got a most severe attack of dysentery, and which he believed to have been produced by contagion. He was not satisfied with Mr. Conolly Norman's observations upon malaria. From the most remote times dysentery had been epidemic in Ireland. In the battles during the reign of Elizabeth the soldiers were decimated by it; the same thing occurred during the wars of Cromwell and William III; and yet Ireland had always been remarkably free from

malaria. But that dysentery might be associated with malaria, on the other hand, was possible. Malaria, as such, was confined to very limited districts in Ireland. He knew that it existed along the Dublin river; but there had been no co-existence of dysentery in those spots. Another remarkable fact was that it occurred in certain seasons of the year. It was well-known to break out in the autumn, especially after the first frosts, which was accounted for in former times by persons drinking water containing animal and vegetable material in a state of decay. As for its mortality, he was resident in the hospital during the years of 1847, 1848, and 1849, and had to attend specially upon fever and dysentery; and the mortality in cases of dysentery—of which only the very bad were admitted—was three times as great as in the worst fever cases; it amounted at one period to one out of every four cases. Dr. Cheyne used the remarkable expression that dysentery was "fever turned in on the bowels." His preparations illustrative of the disease were in the Richmond Hospital, and were described in the series of the Dublin hospital reports. —*British Med. Journal*, February 4, 1888.

Case of Chronic Mercurialism.

At the meeting of the Society of Internal Medicine, February 6, 1888, Dr. Landgraf reported the case of a mechanic, twenty-five years old, who had previously enjoyed good health. Since May, 1887, he had been engaged in carbonizing in a factory which made the loops for Edison's incandescent lamps. The table at which he was at work stood immediately under a large tube which is filled with mercury, and has a small opening from which the mercury flows upon the table. He has often found mercury in his pockets. He admits also that in course of time his dinner kettle has become completely silvered. Notwithstanding all this, the patient was in perfectly good health, until six weeks before Christmas; in other words, after being engaged in this work for six months.

The first symptoms of intoxication were mercurial stomatitis, slight bleeding from the gums, and fetor from the mouth. These symptoms subsided under the use of suitable gargles. Soon after this, uncertainty in the use of the hand appeared. The patient noticed that he became excited; he could still perform his duties, but just as soon as anyone looked at him he became restless, and was unable to work. At last, the approach of his chief would cause him to stop at once in the midst of his work. He quit work in January, 1888, and on January 31 came in his present condition to the Charité. The patient is a strong muscular man, whose internal organs are entirely sound. The pulse is persistently slow, beating 50 or 60 times to the minute, and there is a double sound in the crural arteries. He complains now of stomatitis, slight bleeding from the gums, ulcerations, oppression in the epigastrium; he has no diarrhœa, but rather a disposition toward constipation. His chief complaint is trembling of the limbs. In spite of the strong muscular development of the arms, these tremble violently as soon as they are stretched out. This condition is more striking in the left hand than in the right, and is explained by the fact that the patient was accustomed to work with his left hand. A slight difference is also present in the lower limbs. Sensation is normal. The muscles respond more readily to the electric current than the nerves. Mercury can be detected in the urine, which is, in other respects, unaffected. The manner of the patient is most strikingly changed. In telling of his symptoms he is uncommonly talkative, but he confuses the words, putting one in place of another; this is especially true on the approach of the physician. No noteworthy change in his condition has yet occurred. — *Deutsche Medizinal-Zeitung*, Feb. 13, 1888.

Multiple Abscesses of the Liver and Lungs.

At a meeting of the Royal Academy of Medicine in Ireland, January 13, 1888, Dr. Finny exhibited specimens illustrating pyæmic multiple abscesses of the liver and lungs, which had run a rapid course of about ten days, and in which jaundice and the expectoration of pus had occurred but five days before death. The patient, who had been admitted under Dr. Finny's care into Sir Patrick Dun's Hospital on November 16, 1887, gave a history of having been treated for pain and suffering referred to the left side of the abdomen, over four years previously, and of the question being discussed as to the existence at that time of cancer of the stomach. He died on December 21, and on *post-mortem* examination, in the situation to which pain had been referred, there was found an abscess, shut in by firm and old adhesions of the peritoneum, and limited by the left kidney, the lower third of the spleen, the tail of the pancreas, and the superior surface of the splenic flexure of the colon. The abscess contained a couple of ounces of grumous, cheesy matter. The points of interest were (1) the long

duration (over four years) which had elapsed between the primary inflammation of the peritoneum and its subsequent conversion into an abscess; and, as a corollary to this, the danger, remote as well as immediate, attendant on peritoneal inflammations; (2) the mode by which the secondary abscesses of the liver and lungs were developed, namely, by the pus directly entering the portal circulation through the communication with the spleen, and thence again by the hepatic veins it was carried into the lungs; and (3) the short time which elapsed between the direct infection of the blood and the occurrence of lung abscesses, a period which may be set down as under five days; (4) the formation of the multiple abscesses was embolic in its nature, and accounted for the number and small size of the hepatic abscesses.—*British Med. Journal*, Feb. 4, 1888.

Care of the Insane.

The *Medical Record*, February 18, 1888, contains the following report of the committee of the Medical Society of the State of New York, consisting of Drs. A. Jacobi and C. R. Agnew, to which was committed that portion of the President's opening address relating to the treatment of the insane:

"1. That until comparatively recent times the insane were considered and treated as criminals and confined in dungeons or prisons. 2. Their subsequent retention in poor-houses was but a remnant and mitigation of the old system. 3. The treatment of the insane has improved with the progress of civilization. 4. Therefore special hospitals were supplied for them, and their welfare was intrusted to scientific and humane experts. 5. To return to anything like the old system of treating the insane in poor-houses or relegating them to the custody of county officials would be a grave mistake.

"As early as 1855, at a meeting of the county superintendents of the poor, held at Utica, the following, among other resolutions, was passed:

"'*Resolved*, That no insane person should be treated or in any way taken care of in any county poor or almshouse, or other receptacle provided for, and in which paupers are maintained and supported.'—Fifty-fifth Annual Report, State Asylum at Utica.

"6. For the proper classification and treatment of the insane more means are required than for the patients of general or even other special hospitals. Institutions for the insane therefore demand medical experts as superintendents, nurses trained in the general care of the sick and then in the special care of the insane; schools for the physical and intellectual training of the insane; for the practice of out-door and indoor industries, and many other appliances. 7. The Medical Society of the State of New York expresses therefore its objections to any plan or law which in any way looks to the return of the insane to the county poor-houses as being unscientific and inhumane, and expresses its conviction that those institutions, like the State Asylum, which have boards of managers accountable to the State government and also the public, are best adapted for the care of the insane poor of the State."

The report was adopted, Feb. 9, 1888.

Action of Green Hellebore Upon the Heart and Circulation.

Christovich (*Revista de ciencias médicas de Barcelona*), after testing the action of the watery extract of green hellebore root upon dogs and frogs, gave it to eleven patients who were suffering from heart disease, with disturbed compensation. From these observations he obtained the following results: 1. The contractions of the heart were more energetic, which fact could be recognized by the increased strength of the impulse. The heart sounds were louder, and the pulse waves showed increased tension. In those cases in which a difference existed between the number of contractions of the heart and the number of pulse beats, this difference disappeared or became less. 2. The frequency of the contractions of the heart diminished in those cases in which it had been excessive. 3. Irregularity in the rhythm of the heart contractions diminished in a few cases. 4. Congestive symptoms in the lungs, liver and kidneys disappeared or grew fewer. 5. The quantity of urine was increased. 6. Where dropsies existed, these were removed, and the body weight diminished in consequence.

The author found that complication of heart disease with nephritis considerably interfered with the action of the drug. In two cases an infusion of the root (25 parts to 200) was employed in tablespoonful doses every two hours; and in the remaining cases he gave from 10 to 20 drops of a solution of the extract (one part to 100), from four to six times a day. The clinical observations were conducted under Botkin.—*Deutsche Medizinal-Zeitung*, January 30, 1888.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium,	**6.00**
Physician's Daily Pocket Record,	**1.25**
Reporter and Pocket Record,	**6.00**
Reporter, Compendium and Pocket Record,	**7.00**

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

ERYTHROPHLŒINE, A NEW LOCAL ANÆSTHETIC.

In a communication read before the Berlin Medical Society, last January, DR. L. LEWIN reported the result of his examination into the physiological properties of the African Haya poison, obtained from the bark of the *erythrophlœum judiciale*. His results were incidentally referred to in our Vienna correspondence (REPORTER, March 3). He stated that a concentrated aqueous solution of the poison produced insensibility with some irritation of the cornea, which appeared later than the anæsthesia from cocaine, but lasted for eight or ten hours. It diminished the pulsation of the frog's heart from thirty to eight per minute, and induced paralysis of the extremities. Similar effects were produced in dogs, which also exhibited marked dyspnœa, and peculiar convulsions, affecting the eyelids, the muscles of the trunk and those of the intestines, but not the paralyzed limbs. Then decreasing sensitiveness was observed, and death occurred without convulsions. These effects were more marked when alcoholic extracts of the drug were used. In the pigeon, vomiting, diarrhœa, dyspnœa, convulsions and death were caused by aqueous and alcoholic extracts, injected subcutaneously; but administered by the beak, vomiting and diarrhœa were the only effects produced. Suspecting from the effects, from his knowledge of African poisons and from microscopic inspection of the poison, that the *erythrophlœum judiciale* was the active drug, Lewin obtained erythrophlœine hydrochlorate from Merck, and found that a two per cent. concentrated solution produced, with great irritation of the conjunctiva, contraction of the pupil and insensibility of the eye. Solutions of one-quarter per cent., or even one-tenth per cent., produced after fifteen to twenty minutes anæsthesia of the cornea, without apparent irritation. After injecting the solution of Haya poison under the skin of the Guinea-pig, Lewin was able to cut down as far as the muscles without indication of causing pain. It would seem either that an irritating principle is present which has not been separated from the erythrophlœine, but which is not effective in great dilution, or that the erythrophlœine itself is irritating in all but the weakest solutions.

The anæsthetic effects asserted by Lewin to follow from the local use of erythrophlœine have been confirmed in some degree by other observers. Thus F. GOLDSCHMIDT, in a communication to the *Centralblatt für klin. Medizin*, No. 7, 1888, states that after the instillation into the eyes of rabbits of a one-tenth of one per cent. solution, anæsthesia was produced which continued three or four hours; while if a one per cent. solution was used, the anæsthesia persisted for twenty-four hours. Nevertheless, complete insensibility did not result even from the instillation of several drops of a concentrated solution. In the healthy human eye he found that the weaker solution was sufficient to produce complete anæsthesia, which appeared in about fifteen minutes and lasted three or four hours. No bad effects were noted with the exception of slight conjunctival irritation and a corresponding feeling of burning and heat in the eye; there was no change in the pupil, nor in its reaction, nor in accommodation or sharpness of vision. He successfully employed it in the extraction of some fragments

of iron from the cornea, and in slitting up the lachrymal canal. The operations were painless. Goldschmidt, however, does not think that the drug will find extensive therapeutic application because, unlike cocaine, it dilates the vessels.

A. von Reiss, of Vienna, (*Intern. klin. Rundschau*, No. 8, 1888; *Deutsche Medizinal-Zeitung*, March 1, 1888), substantially confirms these results. Anæsthesia, in his experiments, was not as complete as that following the use of cocaine, while one or two hours after the instillation there was always cloudiness of the epithelial layer of the cornea, lachrymation, hyperæmia of the conjunctiva, and ciliary injection. Deeper lying opacities were also noted, but in twenty-four hours the eye became normal. These results followed the use of a one-quarter per cent. solution. When the solution employed was of a strength of a little over one-tenth per cent., no bad effects were noticed, and partial anæsthesia was secured. A. Königstein (*Internat. klin. Rundschau*, No. 8, 1888), also confirms in the main the result just stated, but thinks that the drug will find no employment in eye surgery.

Finally, at a meeting of the Berlin Medical Society, February 29, 1888, (*Deutsche med. Wochenschrift*, March 8, 1888), Dr. G. Gutmann reported a case in which he had instilled into the eye two drops of a two-tenths per cent. solution, for the purpose of obtaining sufficient anæsthesia to remove a foreign body from the cornea. Anæsthesia developed in half an hour, and the foreign body was removed as successfully as though cocaine had been used. But on the following day there was a very intense grayish-white cloudiness of the whole cornea, which was also quite anæsthetic. This condition continued for four or five days, and even after eight days the cornea was still anæsthetic. From the eighth to the eleventh day the cloudiness of the cornea began to diminish at the periphery. Anæsthesia was demonstrable in the centre of the cornea as late as the fourteenth day, but the cornea had cleared up so that there was only slight haziness in the centre.

Bearing in mind the rise and fall of the alleged local anæsthetics, "gleditschine" and "drumine," it behooves one to be cautious in expressing any opinion bearing upon the probable value of erythrophlœine. It is not at all unlikely that it possesses genuine anæsthetic powers, but the indications are also strong that it may prove too irritating for use upon the more sensitive mucous membranes.

LORETA'S OPERATION: DIGITAL DILATATION OF THE PYLORUS.

What is known by the brief and appropriate name of "Loreta's Operation," consists in making an opening through the wall of the abdomen, into the stomach, and then stretching the pyloric orifice with the fingers. It was first practiced by Loreta, of Bologna, in 1882, and has been done a few times since. The last case reported was done by Loreta, January 30, 1888. The patient was a man fifty-four years old, who had been very intemperate, and who had suffered with dyspepsia since 1872, and with symptoms of stricture of the pylorus since 1880. When examined he was thin, his stomach was dilated, and a hard, fibrous cord could be felt in the region of the pylorus.

In carrying out the operation, Professor Loreta first washed out the stomach with an alkaline solution and then made an incision along the linea alba from the lower end of the sternum to the umbilicus. This exposed the stomach, which was drawn partly out of the wound, and opened midway between the greater and lesser curvatures. The index finger was then passed into the stomach in the direction of the pylorus, through which it could not be pushed. A large urethral bougie and after an œsophageal sound were then passed through into the duodenum. By this means the stricture was so far dilated that the operator was able to get his finger through the pylorus and draw it over almost to the abdominal wound. The index of the left hand was then also passed through on the right as a guide. The pyloric orifice was then dilated by forcible divulsion with the two fingers, a proceeding which the tightness of the stricture rendered very difficult. Finally, the wound in the stomach was closed

by continuous, and that, in the abdominal wall by interrupted, sutures, and an antiseptic dressing was applied. On February 9, the wound was healed, and the patient was completely free from his troublesome symptoms. Digestion was perfect, vomiting had entirely ceased, and the man had lost the look of suffering which had been so marked before the operation. Dr. Bufalini, who reports the case, says that not a single instance of relapse after Loreta's operation has yet been heard of.

We call the attention of our readers to this operation because it is one which has many things to recommend it, and because it seems probable that a greater familiarity with what may be done for patients with obstructions in the course of the alimentary canal might lead to the prolongation of lives imperilled by obstructions. The contents of the abdominal cavity are now so frequently and so successfully operated upon, that there seems to be no good reason why persons suspected of having stenosis of either orifice of the stomach should be permitted to die without an attempt being made to prolong their lives by means of a surgical operation. Only recently a man, with stricture of the lowest part of the œsophagus, died in a city in Pennsylvania, who might have lived longer if his stomach had been opened and the stricture dilated. It is possible that there were reasons for this which have not yet appeared; but it is also possible that, if his medical attendants had been fully aware of what has been done for the relief of such patients, they would have added his case to the number of those in which abdominal surgery has achieved such happy results.

FLEXION OF THE UTERUS AND OBSTRUCTION.

In several recent publications certain writers have opposed the commonly accepted and time-honored view that flexion of the uterus tends to obliterate the lumen of the cervix uteri. Their argument is deserving of great respect, although it leaves unexplained the symptoms so often observed of periods of comparative rest and comfort followed by colicky pains and the expulsion of menstrual discharges, which in their turn are succeeded by periods of rest and the cessation of the menstrual flow. These symptoms are so often present in cases of flexion of the lower segment of the uterus, that the old illustration of a bent elastic tube seems to be applicable to the condition existing in the flexed womb.

This way of representing the mechanical conditions is supported by the appearances found in certain specimens of the uterus which are to be found in pathological museums; and only recently (*British Medical Journal*, March 3, 1888), Dr. Graily Hewitt, of London, has described and pictured such a specimen. This specimen is in the museum of University College, London, and shows an almost total obliteration of the lumen of the cervix in a case of rectangular anteflexion of the uterus. It may be objected to Dr. Hewitt's opinion as to the significance of this specimen, that its long stay in alcohol prevents it from being taken as an illustration of what occurs during life when the tissues of the uterus are soft and pliable. Such an objection is not without force; but within reasonable limits it would seem that the specimen does illustrate the mechanical conditions of a flexed uterus during life; and that they may still be regarded as not materially different from those of a bent elastic tube. This view may be incorrect; but it is not unreasonable, and it harmonizes—as we have said—so well with the rational signs which are features of almost every day observation, that it seems unnecessary to abandon it, until stronger arguments are adduced against it than we have yet seen.

PASTEUR AND PESTILENCE.

It is pleasant to note that the proposition of Pasteur to exterminate the rabbits of Australia by sowing among them the seeds of fowl-cholera, to which we alluded in the Reporter, March 10, 1888, is meeting with the opposition which we hoped it would meet in that country. His agents are said to be on the way to New South Wales; but news comes from that country that heavy penalties will be enforced against persons "who introduce diseased rabbits." This

may not apply exactly to those who propose to introduce disease germs among rabbits already there; but it is to be presumed that it is intended to prevent such a proceeding. We would be glad if the spirit of humanity were as strong in some scientific circles as the spirit of commercial enterprise is, and if the sufferings of the lower animals were not so wholly subordinated, as they sometimes are, to the gain, or even to the ailments, of their masters. But the rabbits of Australia may rejoice that, in this case, what threatens them is regarded as so threatening to mankind that they are likely to be spared the pestilence which Pasteur and his followers intended for them.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

DISEASES OF MAN: DATA OF THEIR NOMENCLATURE, CLASSIFICATION AND GENESIS. By John W. S. Gouley, M.D., Surgeon to Bellevue Hospital. New York: J. H. Vail & Co., 1888. 12 mo., pp. 408. Price, $2.50.

It is by no means easy to review a book like this one by Dr. Gouley. One cannot fail to sympathize with its object, although one may despair of seeing this accomplished. Good work has been done of late in certain special fields of medical observation, and our English brethren have suggested a carefully prepared nomenclature covering the whole ground of medical experience, which might be better known than it is. For all this, there is still an unfortunate diversity in the terms in which medical men express themselves. It is no wonder then that one should be found so desirous of securing uniformity that he would even incur the risks of proposing a new and carefully prepared nomenclature. Such an one is Dr. Gouley. Well aware of the risks refered to, he has devoted four hundred pages to an attempt to root up the growth of centuries and to plant in its stead the production of his own verbal forcing-house. Some of the new plants have a strange look, and may not long survive their transplantation. But this, time will decide. The object of the author is commendable, and we bespeak for his work the sympathetic consideration of those who shall judge its fruits.

—A Brooklyn dentist has succeeded in placing a gold filling in one of the teeth of his five-year-old setter. The method of filling was the same that he employs in treating the teeth of his regular patients. The dog submitted to the drilling of the cavity, the plugging of the gold and the polishing, with little impatience, and did not even object to having her mouth filled with a rubber "dam." The cavity was on the outside and could be worked at easily.

Correspondence.

Masturbation and Onanism.

Editor Med. and Surg. Reporter:

Sir:—I notice in your last number, of the 17th inst., a question asked by your Kansas correspondent, in regard to "masturbation" and "Onanism," or, "if custom had made the two words interchangeable?" I only wonder the question has not been asked long before, which would have brought out the correct answer you have given said correspondent.

But, I would ask, why the author of the leading medical dictionary of this country should have suffered the error to re-appear in his revised new edition? For it was a great mistake; notwithstanding his medical dictionary has been considered as good authority in the medical world as Webster's unabridged dictionary in the English language.

Surely, a little research and study into ancient history would have convinced the most worthy and well-read author that "Onanism" was not "masturbation," but from Onan, of yore, who married his brother's widow, and took means, by partial, or incomplete sexual congress to prevent the consequences of marriage; and sacred history tells us, Jehovah was angry with him and slew him as he had slain his brother,—Gen. xxxviii: verses 8, 9 and 10. Therefore, all believers in sacred history cannot but be convinced that Onan's trespass upon nature was not "solitary vice," or so-called "self abuse." However, in a moral and physical sense we claim it is as *first cousin* to the latter.

I am sorry to feel obliged to assert, that in this Christian age of the 19th century, Onanism is *extensively* practiced both in and out of the church, by married men, who had stipulated before, or at marriage, that they would not have more than one or two children. In every case that has come to my knowledge for the past thirty years, the arrangement has resulted in unhappiness to *both* parties, and in several instances has led to divorce.

If a man treats his wife in that unnatural manner, even at her solicitation, unfaithfulness in one or the other is almost sure to result.

The act of "withdrawing" before ejaculation of semen takes place is also frequently the cause of *early* impotency and other physical debility on the part of the male, and in many instances causing congestion and displacement of the uterus in the female, and nervous prostration too. Also great aversion to the husband, and a desire to be in the

company of other men. In fact, I am confident that Onanism, "self abuse," and excessive sexual congress, have been the cause of as many "domestic hells," which have lead to divorce, as has strong drink.

Yours truly, ISAAC FARRAR, M.D.

Forcible Feeding of the Insane.

EDITOR MED. AND SURG. REPORTER:

Sir:—In an editorial on "Forcible Feeding of the Insane," in the REPORTER of March 10, an approval is given to Rader's opinion that this procedure is not only useless but dangerous. The expression of such views by a journal so widely circulated as the REPORTER is, I believe, to be deprecated; as I am convinced that forcible feeding of both insane and of hysterical fasters is too much neglected at present outside the doors of hospitals for the insane. If the reports of such cases in the daily press are to be relied upon, there is a singular absence of this rational treatment of the wilful fasters whose deaths are so invariably mentioned as a sequel.

For a number of years I was called upon to feed in this way from one to four patients twice daily, and in no single instance was there an untoward result. I do not remember one case that was not rapidly benefitted, both mentally and physically, by it. Of course the violent struggles of new cases (and sometimes of old ones) made it very difficult to pass the œsophageal tube at times, but an occasional slipping of the tube into the larynx was not productive of injury; for real force should never be used, and the sensation imparted by the larynx is readily detected. The use of force to keep an unwilling patient in the proper position on a mattress placed on the floor, should, however, be abundant; as the more force of this kind that is displayed, the less will be really used.

There is one point that deserves correction, and that is the use of the stomach-pump for this purpose. This instrument is too rigid to communicate intelligible sensations to the hand of the operator, and it is impossible while using it to tell whether the stomach is full or not. A rubber hand-ball arrangement is far better; and the best instrument for this purpose is one constructed after the principle of Hall's syringe, in which the motive power is compressed air, and in which there are no valves to be clogged and become septic.

There is no reason for any physician shrinking from a manifest duty to such patients under his charge, as the necessary instruments for the temporary feeding of the case are always at hand. A large flexible male catheter and an ordinary rubber syringe, which may be readily connected by appropriate tubing, answer all purposes until a more suitable apparatus can be obtained. To force the jaws wide enough for a gag, a blunt wooden wedge and patience are often required.

Yours very truly,

G. BETTON MASSEY, M.D.

1706 Walnut street, Philadelphia.

March 20, 1888.

NOTES AND COMMENTS.

England and Quarantine.

The editor of the *Sanitarian*, February, 1888, brings the following severe accusation against the English in their relation to what is called quarantine. They bring, he says, cholera from India to the ports of the Red Sea under cover of a clean bill of health, and distribute it at the seaports on the route. If it be overland, they leave the sick, the dying and the dead to spread the disease round about. They convey it to China and Japan, and, pushing the freedom of commerce against all restrictions, risk its introduction at every port on the Mediterranean into which they can force an entrance. But they are careful not to land it in England.

For, most remarkable of all, while the English denounce all quarantine regulations if maintained in Italy, in France, or in Spain, they enforce the most rigid quarantines at their own ports of any people in the world, even to the extent of entire exclusion, as we have before taken occasion to point out. Yet, so accommodating is England, in this respect, that while she prohibits the entry of infected ships and cargoes at her own ports, she gives them new clearances, with clean bills of health to foreign ports! And when the filthy ships and cargoes thus *forwarded* by English practice arrive at, and infect the seaports of other countries, English preaching is never wanting to make it appear that all the blame rests upon the filthy localities and habits of the people to whom she has sent her infected ships and cargoes. * * * * * Sanitarians who are alive to English practice, as against Englishmen's preaching, with regard to quarantine, will not be misled by the formulated resolutions which are the common stock-in-trade of English delegates at sanitary conferences, or the balderdash of her multitude of assayists for the promotion of commerce in disease. They will look at England's practice at home; be careful to obtain and study the reports of her port sanitary authorities, and learn with wha

care she excludes infectious ships, merchandise and diseases from her own doors; her continuous watchfulness and reports with regard to cholera, especially, at foreign ports; the names and dates of all vessels sailing from such ports, and whence; and her admirable precautions against the introduction of cholera. By thus doing they will acquire knowledge of practical sanitation to which the word "quarantine" is in no respect an index. Indeed, this word should be dropped from the vocabulary of sanitarians everywhere; it is opposed to *practical work* for the prevention of disease, and the time necessary for its exercise and to cover the incubation period of infectious diseases is all the detention that accomplished sanitarians now require anywhere.

Professional Secrets—The Michigan Law Respecting Them.

In the reports of the Michigan Supreme Court for June, 1882, we find the following in a decision written by Judge Cooley:

"A physician was called to the stand, who testified that he treated a young German lady at Benham's hotel in the city of Corunna, in December, 1879, and January, 1880," for a bad case of gonorrhœa, and that he was informed that she had been at work for Riley Storrs. This evidence ought not to be passed over for many reasons. One is that the physician had no business to give it. The statute —Comp. L. 7576—provides that 'No person duly authorized to practice physic and surgery shall be allowed to disclose any information which he may have acquired in attending any patient in his professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or do any act for him as a surgeon.' Every reputable physician must know of the existence of this statute; he must know from its very terms as well as from the obvious reasons underlying it, that it is not at his option to disclose professional secrets. A rule is prescribed which he is not to be "allowed" to violate; a privilege is guarded which does not belong to him, but to his patient, and which continues indefinitely, and can be waved by no one but the patient himself." (Numerous authorities for these statements are cited and the judge goes on to say): "What was done in this case may have been thoughtlessly done; but if a physician is found disposed to violate both the law of the land and the precepts of professional ethics by making such a disclosure, and if counsel invite him to do so by their questions, the commissioner, in the case of so plain a disregard of the law to the prejudice of a third party, may well decline to be an instrument of the wrong."

Such then is the law of Michigan respecting the secrets that come to his knowledge while rendering professional service to any person. They are his only for the benefit of the interested patient. The law specifically forbids his divulging them. This is based upon common sense and the rights of all the interested parties.

We trust that this may come to the knowledge of every physician and that each one may with greater vigilance than formerly observe the law, the morals, and the good sense. We know of instances in which through ignorance of this law, physicians have submitted to brow-beating lawyers and given evidence in opposition to this law.—*American Lancet*, March, 1888.

Formulæ for Iodoform.

Dr. Howard, in *Journal de Médecine de Paris*, gives a list of useful formulæ for iodoform, from which we quote the following:

For syphilitic sores:

Iodoform	℥iij ¼
Thymol	℥ viss
White sugar	gr. xvss

This powder should be well mixed and ground up. At first it should be dusted over the sore two or three times daily. Later (in four or five days) one application daily will be sufficient.

For herpes, a mixture of

Iodoform	℥ j
Oil of eucalyptus	f ℥ iv

should be applied two or three times daily.

In granular inflammation of the eyes the author has used the following formula with great success. The powder should be dusted into the eye by means of a camel's-hair brush:

Iodoformi	gr. xvss
Sacch. lact.	℥ iss

M. ft. pulv.

Chancres, orchitis, etc., may be dressed with the following salve:

℞	Iodoformi	℥ j
	Balsam. Peruv.	℥ ij
	Vaselin. flav.	℥ iss
	Ol. menth. pip.	gtt. viij

M. ft. ung.

The following salve will be found of great value in burns:

Iodoformi	℥ j
Ext. conii	℥ iss
Acid. carbol.	gr. viij
Unguent. rosat	℥ j

—*Therapeutic Gazette*, Jan. 16, 1888.

Suggestions for the Next Revision of the U. S. Pharmacopœia.

A committee appointed by the Wisconsin State Pharmaceutical Association, in a report upon the next revision of the U. S. Pharmacopœia, makes some suggestions which are of interest to physicians. From the *Phar. Era*, February, 1888, we learn that the first portion of the report refers to the nationalization of the U. S. Pharmacopœia, and to some details in the constitution of future revision committees. The specific recommendations offered with regard to the pharmacopœia itself, were as follows:

1. That in the next revision the metric system be adopted throughout, the quantities of the fluid, however, being expressed not in grains but in cubic centimeters. Should this change not be deemed advisable, rather than recede a step, it would be better to retain the present system of parts by weight, "although it is safe to say that three-fourths of the pharmacists prefer measuring liquids to weighing them."

2. That a table of maximum doses of all potent drugs and preparations to be included in the next revision.

3. That the following preparations be dropped: Elixir Aurantii, Liquor Pepsini, Acetum Sanguinariæ.

4. That the following be included in the pharmacopœia: Rhamnus Purshiana, and a fluid extract therefrom; fluid extract and syrup of Quillaia; iodol; menthol; cocaine and its salts; petrolatum carbolisatum of proper strength for the general public; oleum carbolisatum of proper strength for the same purpose; glyceritum acidi tannici, U. S. 1870; glycerites of carbolic acid, gallic acid and of borax (the latter to replace the commonly used honey of borax); tinctura iodi comp., U. S. 1870; unguentum ammonii iodidi of the same strength as the ung. pot. iod.; ether nitrosi pepsinum.

So Called Hendon Cow Disease and Scarlet Fever.

Professor Edgar Crookshank in his further report upon the so-called Hendon cow disease and its relation to scarlet fever (*Lancet*, January 28, 1888) gives the following summary of his opinions: 1. The nature of the contagium of scarlet fever is unknown. 2. The micro-organism regarded by Klein as the contagium is the *streptococcus pyogenes*. 3. The streptococcus pyogenes is found, sometimes in company with *staphylococcus pyogenes aureus* as a secondary result in scarlet fever and many other diseases. 4. A streptococcus was first observed in scarlet fever by Crooke, later by Löffler, Heubner and Bardt; but its exact relation to scarlatina and its undoubted identity with the streptococcus from pus and puerperal fever were definitely established in 1885, by Fränkel and Freudenberg. 5. Both the Wiltshire and Hendon cow diseases were called cow-pox by people on the farms. 6. Both diseases correspond in their clinical history. 7. The ulcers on the teats correspond in naked eye and in microscopical appearances, and the latter "vividly recall the appearances of cow-pox." 8. Calves inoculated from the discharges of the ulcers are similarly affected. 9. Post-mortem examination of such calves, or of calves inoculated with streptococci isolated from scarlet fever cases, show similar appearances. 10. The post-mortem appearances in such inoculated calves are the result of septicæmia. 11. There are no specific visceral changes in cow-pox apart from complications or coincident affections.

In conclusion, Prof. Crookshank promises in a further communication to publish the history of the lad shown at the meeting of the Society, the full details of the calves inoculated from the boy, and of calves inoculated from those calves, the results of revaccination of those calves, and further details from Wiltshire and Gloucestershire.

Traumatic Aneurism of the Internal Plantar Artery.

Mr. Walsham reports in the *Lancet*, January 28, 1888, a case of traumatic aneurism of the internal plantar artery of the left foot following the division of the plantar fascia for talipes equino-varus. The patient was a boy of 7 years, who was operated on in St. Bartholomew's Hospital, on July 12, 1887, for double talipes equino-varus. A sharp hemorrhage followed the operation upon the left foot, but as no subsequent trouble ensued the boy was sent home wearing a plaster bandage. On July 26, he returned, and it was then found that an aneurism had developed. This aneurism was finally cured by pressure upon the posterior tibial artery behind the inner ankle, and by pressure upon the aneurism itself, and by securing the foot and leg to a posterior splint. The patient was discharged November 6. Mr. Walsham remarks that this is the only case in which this accident has happened to him, though injury to the artery is not so uncommon. He believes carelessness on the part of the mother in permitting the child to walk about too soon, is to blame in this case.

Operative Surgery of the Male Bladder.

At a meeting of the Edinburgh Medico-Chirurgical Society, February 1, 1888, Prof. Annandale read a paper entitled, "Clinical Remarks upon the Operative Surgery of the Male Bladder," his object being to express his opinion briefly and from experience as to recent operations on the male bladder. He had performed the supra-pubic operation recommended by Sir Henry Thompson, as well as perineal section according to Mr. Reginald Harrison's method, and had come to the conclusion that the latter was the better, because the bladder was more easily drained, and the incision through the prostate did good. He advocates the operation of perineal cystotomy in the following cases: 1. In cases of constant desire to pass water, accompanied by great pain and enlarged prostate, when the ordinary treatment of catheterization and washing out has failed. 2. In acute retention from enlarged prostate. 3. For removal of tumors from the bladder. In such cases it is better to perform both operations, as greater accuracy in removing the tumor is obtained. 4. For persistent irritability of the bladder. For a fortnight after the operation he introduced a lithotomy tube, which was then changed for a short No. 14 catheter made of soft rubber, to which a tube fitted with a tap could be applied, and this enabled patients to go about their ordinary work after a time. In answer to Dr. Hodsdon, he said the tube had to be taken out and cleaned at intervals, and that there was no leakage along the sides of the catheter. Replying to Dr. Cotterill, he said that in every case he tried to incise the prostatic urethra and then the prostate upwards. The incision into the prostate, which Mr. Harrison makes on both sides, appears to have a beneficial effect in many cases of enlarged prostate.—*Medical Press and Circular*, February 8, 1888.

Personal Nomenclature.

In a letter in the *Buffalo Medical and Surgical Journal*, February, 1888, Dr. J. F. Baldwin gives the following interesting facts: "In the article on 'Nomenclature, Personal,' in 'Wood's Reference Handbook of the Medical Sciences,' occur several definitions of these several operations. As the writer of that article, I may say that these definitions cost me more correspondence than all the other five hundred put together. The definitions of Battey's and Tait's operations are quoted verbatim from letters received from each operator. *Battey's operation*—'The complete extirpation of both ovaries, while yet in a state of functional activity, for the effectual remedy of cases of disease otherwise incurable.' *Hegar's operation*—The same as Battey's operation. *Hegar-Tait operation*—A misnomer of Tait's operation. *Tait's operation*—'Removal of the uterine appendages for physical disease other than cystoma: As the removal of the ovaries and tubes for uterine myoma; the removal of a tube for pyosalpinx, or other disease; or the removal of both ovaries and tubes for chronic inflammatory disease and adhesions.'"

The object of Battey's operation is to bring about the menopause, and thus cure diseases which would be cured by the natural arrival of that period, and, hence, it has been resorted to many times for the cure of various hysterical affections. Tait distinctly disapproves of the operation, as employed for this purpose: there must be *actual physical disease.*

Penetrating Gunshot Wounds of the Cranium.

In a paper read before the N. Y. State Medical Society, February 8, 1888, on penetrating gunshot wounds of the cranium, Dr. Joseph D. Bryant said that hemorrhage should be stopped, depressed fragments of bone and all foreign bodies removed, and the wounds thoroughly drained. Statistics show that of sixty-six cases in which the bullet was removed the mortality was forty per cent., while in one hundred and seventy cases in which it was not removed, it was fifty-seven per cent. Of the recoveries when the bullet was removed, the recovery was complete in forty-one per cent., while when the bullet was not removed it was complete in only twenty per cent.

The ball should be removed immediately, when its situation can be found, but no operation should be made to search for a bullet in an unknown situation. A large, light, rigid probe must be used, and passed without force, best in such a way that the force of gravity will make it enter the bullet-wound. The ball is to be removed by a counter-opening when it lies against the opposite side of the skull, and such an opening will admit of search for and removal of the ball if it has been deflected, and also for thorough drainage. Dr. Bryant described an original method for locating the distal end of a probe passed through a bullet-wound, and recommended the telephonic probe very highly. Horsehair drainage is excellent for wounds entirely penetrating the cranium, and sometimes irrigation. —*Medical Record*, February 11, 1888.

Incontinence of Urine in Children.

In a paper on incontinence of urine in children, read before the Obstetrical Society of Boston, December 10, 1887, Dr. C. W. Townsend stated that of 355 children, 179 boys and 176 girls, taken at random among the lower and middle classes, 77 or 21½ per cent. were found to be incontinent, the limit of normal incontinence being placed at three years. The normal infants were found to stop wetting their clothes under one and a half years of age. Among the points brought out by an analysis of the 77 incontinent cases were: that 42 were boys, 35 girls, that in 47 the incontinence was nocturnal only, in two diurnal only, and in 28 both nocturnal and diurnal. In 63 incontinenee continued from infancy; in 14 it came on after the primary incontinence of infancy had ceased.

In discussing treatment, the uselessness and evil of corporal punishment in the majority cases was spoken of. In regard to the operation of circumcision and breaking up adhesions between the corona and glans, its usefulness was recognized and cases cited, but it was not regarded by any means as always curative, for other causes might be operative. The investigations of Parks, who found more or less adhesions in 80 per cent. of boys under 9 years were mentioned as showing that adhesions are far from being always a cause of the trouble. Where no other cause could be found other than an increased irritability of the bladder, the use of belladonna in full doses till physiological effects appear had generally been found to give satisfactory results.—*Boston Med. and Surg. Journal*, February 16, 1888.

Detection of Strychnine for Toxicological Purposes.

R. A. Cripps proposes the following method: He digests the solid substance in six times its weight of methylated spirit, containing a little tartaric acid. This is done for several hours at a temperature a little below the boiling-point of the spirit. The liquid is then filtered, evaporated, and the residue dissolved in 1 oz. of water, and 20 minims of spirit added. The solution, containing suspended matter, is then repeatedly shaken with a mixture of equal parts of chloroform and ether, until all coloring-matter is washed out. The chloroform washings are rejected, the aqueous fluid is rendered alkaline with ammonia, and again shaken with chloroform-ether to dissolve out the alkaloid, which again is re-extracted with acidulated water, the solution rendered alkaline with ammonia, and the strychnine finally dissolved out with chloroform-ether. The method can also be used quantitatively with very satisfactory results, if the ethereal and other liquids be washed by a second or even a third treatment with the solvent employed. To test its accuracy 0.9 grain of strychnine was introduced into a dead cat, and the stomach, etc., treated as described; 0.85 grain of pale yellowish well-defined crystals was obtained.—*Chemist and Druggist*, Feb. 4, 1888.

To Relieve Writers' Cramp.

"Canseur," in the Boston *Herald*, being asked by a correspondent for a cure for writers' cramp, replies that he is unable to name one, but offers these suggestions: Change all the conditions frequently, the height of the chair or of the table, the kind of paper, using sometimes the smoother, sometimes the rougher sort. Have every description of pen and penholder at hand, and change them frequently. Don't try to write a handsome hand, for that is something that a person who has writers' cramp in perfection cannot do. Be satisfied with legibility, and this there need be no difficulty about. The trouble seems to be a nervous one, and very little things will affect it. The change from paper that is ruled to paper that is not, and *vice versâ*, will always give relief, and even a change from black ink to blue has been known to be beneficial. Of course, you must have quill pens in your assortment, but their exclusive use will not help you. A friend who does a great deal of writing has turned to the type-writer for relief, but that is all that it affords. The fingers have got into the cramp habit, and in time the use of the type-writer wearies and stiffens them. Nothing but an infinite variety of appliances, constantly changed, will afford the desired relief.—*Ledger*, Feb. 27, 1888.

Antipyrin in Noctural Emissions.

Dr. Thör, of Beucharest, finds antipyrin an excellent substitute for bromide of potash in nocturnal emissions, being free from the objection to which bromide is liable, viz., that of producing acne. He prescribes from seven to fifteen grains in the form of tablets just before going to bed. Again, in cases of the so-called sexual neurasthenia of Beard, the same drug has proved very useful, but larger doses are required. Dr. Thör commences with fifteen grains a day, and gradually increases this to thirty grains.—*Lancet*, February 18, 1888.

Medical Men and their Fees.

The English journals announce the decision by Mr. Justice Stephen, of the Queen's Bench, of a case which is of much interest to physicians. It seems that Mr. Coumbe, a surgeon, residing at Twyford, claimed $1000 for professional attendance on Colonel Brodhurst. The latter had met with an accident on the road, which resulted in a comminuted fracture of the thigh, the treatment of which was carried out, at his request, at Mr. Coumbe's house, where the patient, with his wife and a nurse, remained some eight weeks. Sir R. Hanson having assumed the responsibility for any liabilities incurred in the treatment, sent a check for $500 on receipt of the bill, and the action was for the balance. The charges included $445 for medical attendance and $50 a week for the board and lodging of Colonel and Mrs. Brodhurst and the nurse. There were also two visits to Brighton, charged at $100 and $78 respectively. A Dr. Waugh and a Dr. Roberts gave evidence on behalf of the defendants to the effect that the charges were too high, but the jury gave a verdict for the plaintiff for $275 beyond the $500 already paid, and the $125 paid into court by Colonel Brodhurst. It was in evidence that Colonel Brodhurst was cured without deformity or disability.

Unsuccessful attempt to Blackmail a Druggist.

An attempt to levy blackmail on a pharmacist was recently made in Kieff by two young men, who are supposed at one time to have been chemist's assistants, or, at all events, to have known something about the business. They each procured from medical men, who of course had no idea that they were not treating genuine patients, a prescription. One of these ordered the preparation of an ordinary harmless mixture, the other was for an atropine lotion. They were taken to the chemist who was to be victimized, and after they had been made up the labels on the bottles were surreptitiously changed by the young men, and the unfortunate chemist threatened with a prosecution for gross and dangerous carelessness, with the object, of course, of obtaining blackmail from him as the price of not being denounced. Fortunately, however, the victim was not so easily caught, and the trial ended in a manner little expected by the young men. It was found out that they had previously played, or attempted to play, a similar trick on chemists in Moscow, and had been successful in obtaining blackmail to the extent of about 250 dollars. They were ordered to be sent to Moscow.—*Lancet*, Feb. 4, 1888.

Prohibiting the Sale of Secret Medicines.

A bill which practically prohibits the sale of secret medicines has been introduced into the Assembly of the State of New York by Mr. J. W. Smith. It provides that no person or firm shall sell any medicinal preparation without filing the formula of the preparation with the State Board of Health and receiving a license or certificate from that body. It further provides that no so-called secret or proprietary medicine shall be sold, unless there is a printed formula showing the nature of the compound on the bottle, and also the words, "Sale authorized by New York State Board of Health."

It seems a very simple and manifest proposition that the public should be protected against the enormous swindling of the patent-medicine trade. And such a bill as the above would certainly promote the public good. But we fear that vested interests will prove too strong for it. The propriety of a printed indorsement by the State Board of Health might be questioned, in any event.—*Medical Record*, March 3, 1888.

Abscess in the Middle Ear mistaken for Toothache.

In the *St. Louis Med. and Surg. Journal*, March, 1888, Dr. A. D. Williams says: "Early in February a young man had what he took to be toothache on the right side of the upper jaw. He consulted a dentist, who could find nothing wrong with the teeth and referred him to me. On examination I found a well-marked abscess in the right drum. The upper back portion of the membrane was bulged outwards to the extent of a pea. When punctured, pus escaped at once, and when air was blown through the drum considerable more was forced out of it. I need hardly add that this promptly relieved the "toothache." Reflex irritation between the teeth and the ear is usually from the former to the latter. In this case the usual order was reversed."

Monobromate of Camphor in Epilepsy.

Dr. Campbell Black recommends the following formula in the *British Med. Journal:*

Monobromate of camphor.....37½ grains
Extract of belladonna.....6 "
Extract of gentian, q.s. to form pill mass.

Divide into 12 pills. One to be taken morning and evening, or in severe cases, three times a day.

Typhoid Mortality in France.

According to the *Lancet*, February 4, 1888, M. Chamberland, chief of M. Pasteur's laboratory, has been writing an important report demonstrating the unsatisfactory character of hygiene in France. He finds that in the French army typhoid fever kills no less than 3.78 per 1000, while the typhoid mortality in the English and German armies is 0.84 and 0.19 per 1000 respectively. Again, the deaths from this disease per 100,000 of population are 63 in Paris, 148 in Marseilles, 19 Brussels, and 17 in Berlin and London. A critique on this report, published in a Lyons medical journal, points out that, in addition to faulty hygiene, antiquated methods of treatment usual in France may have something to answer for. In Lyons, which is the only French city in which the cold-bath treatment of typhoid is much practiced, the typhoid mortality per 100,000 inhabitants is much lower than in Paris, being variously estimated by M. Chamberland and his critic at 42 and 31, per 100,000.

Charming Away Warts.

"In visiting a country asylum, some years ago," writes Dr. Luke, "my attention was directed to several of the patients and nurses who were pestered with warts, and I solemnly charmed them away within a specified period. I had quite forgotten the circumstance until, on re-visiting the institution a few months after, I found that my practice had been followed by the desired effect, and that I was regarded as a real benefactor."—*Southern California Practitioner*, February, 1888.

The Age for Revaccination.

The Local Government Board has issued an order reducing the age limit for revaccination from fifteen to twelve years, under ordinary circumstances, and to ten years in case there be any immediate danger of smallpox.—*Lancet*, February 18, 1888.

Forty Years a Physician.

On March 13, 1888, Dr. James L. Stewart, one of the best known physicians of Erie, Pa., had the pleasure of gathering round him a large number of friends to celebrate the completion of his fortieth year of work in the medical profession. The celebration took the form of a dinner, followed by speeches of praise and congratulation, and the reading of a large number of letters from admiring friends in different parts of the country.

A full account of the proceedings was published in the *Erie Weekly Dispatch* of March 14.

NEWS.

—The Long Island Medical College Hospital held its annual Commencement March 9, and graduated a class of thirty-six.

—The Bellevue Hospital Medical College held its Commencement March 12, and graduated a class of one hundred and forty-four.

—Dr. Edward P. Davis has been elected Attending Obstetrician, and Dr. Wharton Sinkler Neurologist, to the Philadelphia Hospital.

—Sir Henry Acland has been obliged to submit to an operation for hemorrhagic glaucoma of the left eye. He is reported to be doing well.

—The 36th Annual Commencement of the Woman's Medical College of Pennsylvania, was held at the Academy of Music, March 15, 1888. Dean Bodley delivered the address to the graduates.

—Dr. Bramann has had the Commander's cross of the Hohenzollern House Order bestowed upon him by the late Emperor of Germany, for his skilful performance of tracheotomy upon the Crown Prince.

—A dinner to Prof. Agnew, on the completion of the 50th year of his doctorate, will be given by his colleagues in Philadelphia, in the Foyer of the Academy of Music, April 6, 1888, at 7 P.M. It has been decided to ask Dr. Agnew to sit for his portrait.

—Professor Austin Flint will deliver the annual oration before the Alumni Association of Jefferson Medical College, in the amphitheatre of the Hospital, on the evening of April 2. After the oration he will be given a reception at the Hotel Bellevue.

—A society has been formed in Paris for the purpose of special study of diseases of the mouth. This "Stomatological Society" has given occasion to different journals to grow witty over the possibilities in nomenclature which may arise from this tendency to sub-division in titles.

—The Royal Academy of Medicine and Surgery of Barcelona, announces that the Gari prize of $300 will be awarded this year for the best essay on the Pathogenesis of Gonorrhœa, giving clinical forms of the affection, with special reference to prolonged cases and cases of repetition; concomitant and consequent affections; prophylactic treatment. Illustrative specimens are to be sent with the thesis, which must be sent accompanied with a motto in the usual way. The essays may be written in Spanish, French, or Italian, and must be sent to the Academy before June 30, 1889.

HUMOR.

In order to cure whooping-cough in Warwickshire, England, they cut a piece of hair from the nape of the child's neck, chop it very fine, and spread it on a piece of bread and give it to a dog.

Bobby—Ma, did the doctor bring me in the daytime or nighttime? Mother—In the nighttime, Bobby. Bobby—Well, I guess that's the reason I don't remember anything about it. I must have been asleep.

Sorely Affected.—Mrs. Cloony—I'ts sorry Oi am t' hear Mike do be shick, Norah. Pfwhat ails th' man? Mrs. McManus—Keen fer him, Kathie, keen fer him. Th' docther's after sayin' he has a mannerism an' th' hear-rt av him.—*Tid-Bits.*

Anxious Arkansaw Mother.—"Tommy, is that a green persimmon you air eating?"

"Yes, maw."

"Don't you know it ain't healthy to eat green persimmons on an empty stomach?"

"I ain't eatin' this green persimmon on an empty stomach; I ate a peck of 'em before I tackled this one."—*Texas Record of Medicine.*

Tramp (to fussy old gentleman): "Will you please give me ten cents, sir; I'm starving?"

Fussy old gentleman (producing a bill): "Dear me, starving. Can you change a dollar?"

Tramp: "Yes, sir."

Fussy old gentleman (pocketing the change): "Dear, dear, starving! Bless me, but this world is full of misery!"

Almost given away.—Prospective buyer—"You're sure there's no malaria here?" Real estate agent—"Not a s-s-sign of it." Prospective buyer—"No chills and fever?" Real estate agent—"Ain't b-b-been none in t-t-t-t (excuse me) twenty year." Prospective buyer—"Look here, my friend, what makes you tremble so?" Real estate agent (as another wave of shakes passes over him)—"I was a-a-fraid you were g-g-goin' away without buyin', sir."—*Puck.*

OBITUARY.

CARY R. CLEWELL, M.D.

Dr. Cary R. Clewell died at his home in Telford, Pa., March 8, 1888. He was graduated from the Medical Department of the University of Pennsylvania in 1887.

JOHN M. TIMMONS, M.D.

Dr. John M. Timmons died in Whaleyville, January 15, 1888, of phthisis. He was born September 7, 1859, and was graduated from the Jefferson Medical College in 1883. He practiced in Philadelphia till the fall of 1886, when his health failed. He travelled through the West and South for his health, but deriving no benefit returned to his home in Whaleyville, where he died.

F. R. S. DRAKE, M.D.

Dr. F. R. S. Drake, of New York, died in New York, March 11, in the forty-third year of his age. He was graduated from the University of the City of New York in 1871, and was for a time Professor of Clinical Medicine in that College, and visiting physician to the Bellevue Hospital.

WILLIS W. FRENCH, M.D.

Dr. Willis W. French died in New York, March 11. He was graduated from Bowdoin College in 1878, and from the College of Physicians and Surgeons, New York, in 1883.

CHARLES G. STEELE, M.D.

Dr. Charles G. Steele died in Buffalo, N. Y., February 11. He was graduated from the Medical Department of the University of Buffalo in 1886. He was business manager of the *Medical Press of Western New York.*

HENRY P. AYERS, M.D.

Dr. Henry P. Ayers died in Fort Wayne, Indiana, December 28, 1887. He was graduated from the University of the City of New York in 1846.

Official list of changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from March 18, 1888, to March 24, 1888:

Col. J. H. Baxter, Chief Medical Purveyor, will proceed to Augusta Arsenal, Ga., on public business. S. O. 62, A. G. O., March 16, 1888.

Major Wm. C. Spencer, Surgeon, died March 22, 1888, at Fort Trumbull, Conn.

Major Chas. R. Greenleaf, Surgeon, will proceed to Cambridge, Mass., on official business. S. O. 62, A. G. O., March 16, 1888.

Major W. H. Forwood, Surgeon, granted one month's leave. S. O. 20, Dept. Dakota, March 10, 1888.

Major H. E. Brown, Surgeon, assigned to temporary duty at Fort Banancas, Fla., during the absence on leave of Assistant Surgeon M. C. Wyeth. On the return to duty of Capt. Wyeth, Major Brown will rejoin his proper station. S. O. 65, A. G. O., March 20, 1888.

Major R. M. O'Reilly, Surgeon, will proceed to York, Pa., and make an examination of Capt. Edw. B. Rhum, 21st Infantry. S. O. 62, A. G. O., March 16, 1888.

Capt. J. C. Worthington, Assistant Surgeon, granted leave of absence for four months, to take effect May 15, or as soon thereafter as his services can be spared. S. O. 65, A. G. O., March 20, 1888.

Capt. M. C. Wyeth, Assistant Surgeon, granted leave of absence for two months, to take effect about April 1. S. O. 65, A. G. O., March 20, 1888.

There have been no changes in the Medical Corps of the Navy, for the week ending March 24, 1888.

WHOLE No. 1623.] APRIL 7, 1888. [VOL. LVIII., No. 14.

PHYSICIAN of 9 years experience in country practice would like partnership or position as assistant to well established Philadelphia physician. Address, **C. P. JACKSON, 1634 N. 15th St., Phila.**

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

JOSEPH ZENTMAYER,

CASE OF SUCCESSFUL SIMULTANEOUS TRIPLE AMPUTATION FOR RAILWAY INJURY, WITH REMARKS ON THE TECHNIQUE OF MULTIPLE AMPUTATION.[1]

BY JOHN ASHHURST, JR., M. D.,

PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF PENNSYLVANIA; SURGEON TO THE PENNSYLVANIA AND UNIVERSITY HOSPITALS, PHILADELPHIA.

The patient is brought before the College largely on account of the rareness of simultaneous triple major amputations. It is quite possible that some of the Fellows may not have had an opportunity of seeing such a case.

The patient is a Moor, twenty years of age. He was admitted to the University Hospital, November 28, 1887, having been run over on the Pennsylvania Railroad. I saw him within two hours after his admission. I found a compound comminuted fracture of the right leg, the laceration extending above the knee; complete avulsion of the left leg, the limb having been torn off in its lower third; and a compound fracture of a severe character of the right hand and wrist. There was also a compound fracture of the skull, involving the frontal bone. This, however, was an impacted fracture, of course without much depression, and did not require interference. In addition to these injuries, there were numerous brush-burns and contusions, some of a grave character. One upon the left buttock was so severe that the separation of the slough left a cavity fully two inches in depth. Notwithstanding these serious injuries, the patient's general condition was very good; he had reacted thoroughly, and his axillary temperature was 99° F. Under these circumstances, I felt justified in proceeding to the immediate removal of the injured limbs, and amputated successively the right thigh by the antero-posterior flap method; the left leg, about its middle, by a modified Sédillot's external flap operation, the modification consisting in making both flaps from without inward, instead of cutting the external flap by transfixion; and the right forearm by an oval incision, making use of the uninjured skin of the back of the hand and wrist. Certain variations from the ordinary procedure in amputations I shall refer to when I come to speak of what I have ventured to term the technique of multiple amputations. After the operations were completed, the temperature had fallen only to 98° F. The patient had no bad symptom and rapidly recovered, and as you see him now all his wounds are perfectly healed, and he is entirely well.

I have collected some statistics of synchronous multiple amputations. I am able to find but one instance of *quadruple* synchronous amputation—a case in which the operations were done for frost-bite by Dr. George E. Jackson, of Dakota. There are several cases recorded of quadruple amputations, not synchronous, the one which approaches nearest to a synchronous operation being that of Champenois, a French surgeon, who amputated three limbs on one day, and the fourth a few days later.

Of synchronous triple amputation there have been reported four successful cases, not including that presented to-night; one by Dr. Köhler, of Schuylkill Haven, Pa.; one by Dr. Lowman, of Johnstown, Pa.; and two referred to by Professor Agnew, in his *Surgery*, one occurring in the practice of

[1] Stenographic report of a verbal communication made to the College of Physicians, March 7, 1888.

Dr. Stone, of New Orleans, and the other in York, the name of the surgeon not being given. There are reported four or five triple amputations not synchronous. I have myself resorted to synchronous triple amputation in two cases. Several years ago, I had occasion to perform this operation, removing both legs and the right forearm of a man, aged forty-five years, of intemperate habits. The patient died on the tenth day, the fatal result being due rather to the visceral lesions resulting from alcoholism than to the operation.

Double amputations are comparatively numerous. I have personally performed fifteen such operations, this number not including two successful cases of double partial amputation of the feet. I have done fifteen double major amputations, of which five have ended in recovery. One of the patients who recovered, I had the honor of exhibiting to the College some years ago; the amputations in this case were through the right hip-joint and through the left leg. In the fatal cases, seven of the deaths occurred within less than one day, and were, therefore, the immediate result of the shock of the injury and of the operation. Three patients died, one in three days, one in four days, and the third in eighteen days. The latter would probably have recovered, but that he also had suppurative disease of the middle ear, which appeared to be the cause of the pyæmia which proved fatal; for when the stumps were examined, after death, they were found to be in good condition.

With regard to what I have termed the technique of multiple amputations, there are some points which my experience justifies me in urging upon surgeons as of importance in promoting success. In the first place, it is very important that the time occupied by the operations should be brief; that the operations should be done systematically, so as to keep the patient under the anæsthetic as short a time as possible. The next point, perhaps of even more importance, is to keep up the temperature of the patient during the operations. I have been led to think that this is, perhaps, of more importance than anything else. Of course, loss of blood must be scrupulously guarded against, and loss of blood directly causes loss of temperature. In this case hot cans were kept around the patient during the entire operation; and, in order to save time, I operated systematically, the tourniquet and Esmarch bandage being both employed to prevent any loss of blood. I began with the most serious injury, and this is, I think, a point of importance. It may happen that, after the removal of one limb, it will be found that further operation must be postponed on account of the patient's condition, and then it is, of course, better to leave him with the less severe injuries. In this case, I began with the thigh. After amputating the limb, I secured the main vessels, which were readily found. I attempted to tie the arteries with catgut, but as the ligatures broke, I substituted silk, and, in order to save time, left both ends uncut. I next amputated the right leg, securing the vessels in the same manner, and then passed to the forearm. I then came back to the right thigh, screwed up the tourniquet and removed the Esmarch bandage, and secured all the vessels that required ligature, then passing to the other limbs in the same order as before. After the vessels had been secured in each case, a towel dipped in a hot antiseptic solution was placed between the flaps. The wounds were then dressed in the same order, and in this way the operation was completed in a comparatively short time.

The points which I have mentioned I believe to be of great importance, and I think that much of the disappointment of surgeons from these operations is due to a want of attention to these matters.

I should also say that, in order to preserve the bodily heat, I did not use irrigation during the amputations. I think that this often seriously reduces the temperature; and even in comparatively slight operations where it has been used, I have seen the temperature fall to 97° F., and even 95° F. I think that in any grave case, it is better to omit it and to rely upon washing with hot antiseptic solutions before and after the operation. Also, the packing of wet towels around the seat of operation, as is very commonly done, tends to depress the temperature, and in grave cases should be omitted.

I think that it is to an observance of these precautions that I have owed success in this case, and in many other serious operations of various character.

—A party of soldiers in Paris was engaged in firing blank cartridges, when one of them, Carre, put a bullet into his rifle by mistake. When the word was given, Carre, who was in the rear rank, fired with the rest, and his bullet lodged in the head of his front-rank man. The captain in charge dropped dead from heart disease when he saw the soldier fall, and Carre endeavored to kill himself, but was prevented. The bullet was successfully extracted, and the injured man will probably recover.

ESSENTIALS: NON-ESSENTIALS.

W. M. HEPBURN, M.D.,
FREEHOLD, N. J.

A feeling bordering on despair must sometimes fill the heart of every earnest student and practitioner. Difficulties meet him, both in his reading and in his efforts at the bedside, which seem insurmountable, and make him wonder just what he knows about drugs, and doubt if there is much to know. Like the able writer in the *Record*, August 21, 1886, in the article, "What Can We Cure?" who sums up his list of lithontriptics, emmenagogues, expectorants, etc., as worse than useless, and also adds: "Ringer is quoted as a believer in specific medication, while his book goes through six annual editions, yet his most vaunted remedies are for functional disorders. A good physician's highest hopes are realized when he has by opium assuaged pain, and by alcohol kept the heart wagging in the decline of some violent malady."

He even robs us of what a prominent surgeon once remarked to me, were all the drugs we could see results from, viz., iodide of potassium and mercury, quoting Diday as saying: "Syphilis is cured by the grace of God;" and he deals the final blow in these words:

> "Like blind men fighting in the dark,
> They never fail to miss the mark;
> When death doth fail, the doctor's sure
> To meekly stand and claim the cure."

It is not alone in the materia medica and therapeutical world that we are met by such truths, or partial truths. If we try to acquaint ourselves with the cause of disease, we find the same apparent difficulty in knowing just what to accept and what reject. We may give our whole belief to the theories of some brilliant writer, but that does not settle the matter. What is the truth? That is what we wish to know.

In a gathering such as the International Medical Congress, we have an opportunity to see how diametrically men differ. As I read my journal to-day in regard to pneumonia, I find one writer says: "The day is seemingly not far distant when we shall speak of pneumonic fever in precisely the same way as we use the term enteric fever at present; that is, to signify a zymotic or specific blood disease manifesting itself after the lapse of a certain time—the period of incubation—by physical phenomena, objective and subjective, connected in this instance with the lungs." Yet the very next essay is by one who thinks that nearly all of the pneumonias seem to be accounted for without the necessity of supposing a special contagion: cold, dry air, according to this writer, is the great factor in acute pulmonary inflammations.

But why multiply cases? Even in regard to bacteriology, we are informed by an authority, that the only experiments made which have given satisfactory results are those in carbuncle and tuberculosis. As the same writer says: "To conclude hastily that this or that microbe is the cause of any disease is but to ignore or set aside experimental method. The demonstration which the experimental method demands in this case would be complicated, because we would not only have to know that the microbe existed, but we would have to know what was the condition of the blood necessary to the culture of that particular microbe; and science tells us that, for the present, this is a problem we cannot solve." When the innumerable facts of our medical world face us, when we are met by such an array of truths, and attempt to even contemplate the amount of research it will necessite before we see clearly, and not through a glass darkly, we feel our helplessness, and can appreciate the old professor's view of his life which has been spent in the study of one Greek word, and which he thought had been too broad a subject.

But although we see the difficulties, yet we have patients lying on beds of suffering, and, maybe, death. Our *lack* of knowledge cannot be of benefit to them. In our ignorance what are we to do? Certainly the best thing to do is to grasp what has been given to us in the present state of medical knowledge, and to be able to appreciate what is essential, and what not. I truly believe that drugs are meant to be more than mere palliatives; that they have virtues which should make them curative, but that we will never learn what those virtues are until we have first had *preventive* measures *ground into us*. Surgeons performing operations realize the necessity of banishing everything of a contagious character; the dangers of an operation unless they are vanished, but it is hard to impress upon physicians, as a whole, especially when they have pure country air about them, that it is *the* treatment of the present time.

How many perfectly isolate cases of scarlet fever, measles, diphtheria? How many disinfect typhoid and all suspicious stools? How many rooms are thoroughly disinfected after contagious diseases?

I recall a house where last spring I attended three cases of severe attacks of scarlet fever,

in the poorer part of the town. Just while it was at its height I happened to see a large wagon filled with clothes stop there and the driver take a bundle into a room but a little distance from where the patients were all lying. This bundle of cut cloth was to be sewed and then sent back to the factory. I imagine what the result might have been had I allowed the cloth to be left. This house consisting of two rooms filled with old furniture, must have been saturated with germs. I spoke earnestly to the inmates and to one of the health authorities about having the house thoroughly disinfected. I do not think it has been done. And is it an unusual case? Are the great majority of infected houses properly disinfected?

So in another house where two of three children died of diphtheria, a neighbor came unasked and not needed, to sit where the children were. I told her to go home, and was answered that she had been with such cases before and was not afraid, yet she went directly from there to her nursing baby. What an absurdity to pour iron and potash, or any other drug down the throats of the children of such parents. We do not see results as rapidly, from proper care of cases, as does the surgeon; but just as primary union is the usual instead of the exceptional result of operating in the present day, because of vigorous attention to proper surgical surroundings, so will our mortality list be larger or smaller according to our ability to appreciate and rectify the harmful surroundings of our patients. The ignorance in regard to hygiene is appalling. A patient complained to me of his well-water tasting and smelling badly, and on investigation I found his neighbor's cesspool was only twenty-five feet away, and had been there for years. Yet this same neighbor—a man standing well in the business world as a man of sense and sagacity—was amused to think that his cemented cesspool which, though old, was twenty-five feet away, could contaminate the well.

But our knowledge is limited, and as we have diseases which, to us, are non-contagious and non-preventable, what can we do for them? Are opium and alcohol our only standbys? Immediately the fact presents itself that mere prescribing is not the whole duty of a physician. And when we speak of curing disease we connect with that expression the thought of work thoroughly done. Pure air, perfect isolation, suitable and nourishing food, good nursing. How much this means. "High and low, rich and poor, the wise man and the fool, rival in ignorance of the absolute need to health of a limitless supply of fresh, pure air. Their dainty stomachs will reject unsavory food, their delicate hands shrink from the touch of unclean things; but they will greedily and recklessly take into their lungs to be incorporated in themselves viler nuisances than any of the visible filth they have smelt or touched or tasted, for notwithstanding its æriform condition it is as much filth as the fetid ooze of the sewer or solid putrescence of decomposition." Rich and poor suffer from ignorance in most matters where the health is concerned. As one says in regard to Bobbie's eating: "Nobody thinks of refusing to give him kidney, fried potatoes, buckwheat cakes, or coffee. His mother could not decide if questioned, which of these is wholesome fare for infants * * * He lives through it? Why—yes—generally. That is, he does not always and immediately die as the unmistakable result of the poison. His system takes care of it somehow, or gets rid of it somehow else. If, by the time he is thirty, the long suffering stomach will pay no more debts of his contracting, who reckons why the trial-balance does not come out right? He lived through scarlet fever, but it left him slightly deaf; the measles kept him prisoner all of one winter, and his eyes have been weak ever since * * * Not even the always vigilant mother thinks of associating childish excesses with the lad's sick headaches or the man's defective digestion."

In spite of what we do not know how our field broadens as we contemplate our duty; what evidences we gather by simply opening our hearts to them, of the needed medical educators, oh, and how it adds to the dignity of our noble profession to be, not alone drug prescribers—even though they be specifics—but the health *preservers* in the families which we attend.

But more than this as an eminent writer says: "Indeed, the methods, even those the outcome of the most conclusive experimental science and of the most perfect mechanical treatments, must ever take cognizance that in treating the sick we are dealing with the man in disease, *quite as much* as the disease in the man. However more exact our means, however larger our resources, the personal something in the sick, the personal something in the physician will never cease to have their power. And the greatest success will always be with the greatest measure of tact, with the quickest appreciation of vital strength, with the magnetic influence which instils confidence and trust with the fullest inspiration of hope, as well as with courage that knows when to take risks and the wisdom that knows when to rest."

But there are many more facts confront us outside of care for our patients and the personal magnetism of the physician.

One of these is the question of the use and effects of drugs. One reason we do not see *direct* results from medication is because we fail to recognize the disease.

When in the Pennsylvania coal region I recall being requested, by a woman, to give her some ointment for hemorrhoids as her husband had suffered and was then suffering from them. The ointment, with advice as to care in other respects, was given. Next day I was again stopped, as I passed through the town, and requested to give something better. Fortunately I decided to go in the house and see the patient. Examining the parts and not seeing evidence of much trouble, I introduced my finger into the bowel and feeling some hard body lying across the bowel; I passed my finger above and around it (causing great pain) and pulled out a splinter of wood at least one and one-half inches long, blunt at one end and pointed at the other. The man could give no history whatever to account for its presence.

A second reason is, it is sometimes impossible to know just what causes the trouble. I have a patient, an adult, who four years ago fell while walking on the street and had a severe convulsion. It was his first and last. The heart and urine were examined, but nothing abnormal was detected, and a heavy meal was supposed to have caused the attack. A few months since he developed hemianopsia.

Thirdly, even when we detect the disease we do not always do reasonable things. It is seldom one meets a physician who cannot tell him about the latest drugs; but one cannot have much knowledge of the treatment of many doctors without being conscious of the fact that there is yet a wild search after "that specific," and often the poor sufferer is taking three or four distinct combinations, and, as I have seen, *not a teaspoonful* of nourishment.

But how is it possible to speak of the questions which present themselves to the physician in every very sick patient which he must answer for himself, which books cannot aid him in, and on his treatment may depend the life of the person. I have now a convalescent case from that common disease, acute articular rheumatism, which presented just such questions. A man about 28 years of age, German, evidently a sufferer in early life from Pott's disease. Had once before had a long, tedious attack of rheumatism. By exposure he was prostrated in December, and when I saw him he was entirely helpless. From the first he showed symptoms of great prostration. Pulse rapid and weak, breathing short and about thirty respirations to the minute, pain excessive. Gave alkalies, anodynes and food. Retained his food and medicine nicely, but the opiates caused obstinate constipation, and after some days his breath became very offensive, tongue heavily coated and dry, and vomiting threatened—which same would have made his chances few. What shall we do? I gave, with difficulty, an enema. He retained it and had no movement. A purging would cause intense pain from repeated use of bed-pan, and his prostration was too great to allow of it. Decided on one-tenth grain of calomel every hour for six hours, followed by teaspoonful doses of magnes. sulph. every four hours. Result, moist tongue, better digestion, and easy and large movement. If we do well in all such emergencies do we not assist in curing the patient?

As to the specific action of drugs, I know of no specific for any disease, but I have seen drugs act like specifics.

Certain medicines will do well in certain people, and utterly fail in others. Certain drugs will accomplish desired results when combined, when separately they are seemingly useless. I have seen persimmons and whiskey combined literally raise up a man suffering with cancer of the bowel, control a desperate diarrhœa and prostration, when stimulants with anodyne sedatives and everything else utterly failed. In other cases the combination had no good effect.

A case of chorea of very unusual severity markedly and rapidly improved by the use of *strychnine* after *all* the usual and unusual remedies had been tried in vain. We will yet learn *why* these things are so. At present we are necessitated to be empiricists in much of our treatment, but the thoughtful, observing, practical physician learns more every day what is essential and what not, and in using his knowledge does aid in curing disease.

—Dr. F. M. Hamlin, a prominent physician of Auburn, N. Y., was removed to an asylum at Utica, on March 23, as a victim to the morphine and cocaine habit. He was an expert microscopist, and a year ago was commissioned by the British Government to go to the Bermudas and investigate the causes of the onion blight. He made an elaborate report. For several years he has made a study of the morphine habit and has made a specialty of treating patients addicted to it, and notwithstanding this fact has succumbed to the habit himself.

ELECTROLYSIS *VERSUS* OÖPHORECTOMY.

BY WILLIAM R. D. BLACKWOOD, M.D.,
PHILADELPHIA, PA.

For some years past I have intended suggesting the use of strong currents of electricity with a view to destroy the functional activity of the ovaries, but other matters have occupied my time and prevented my doing so. The communication of Dr. Kimball, in the REPORTER for March 3, has renewed my desire to offer the experience resulting from four cases in which ovulation has, I believe, been thus destroyed. The relation of menstruation to ovulation has not been settled yet, nor has it been demonstrated that the menopause depends upon the ceasing of menstruation or ovulation alone. Surgical removal of the ovaries and the tubes does not invariably prevent the monthly flow, although it usually does so. I have seen well-defined menstruation occur in women who have undergone ovariotomy, and Tait's operation singly or combined, and although the flow was neither free nor regular it was considered by the women as menstruation, and to me it was such. I do not believe that electrolysis would be advisable in many cases, nor would it supplant the furor for doing abdominal section, which so many young men (and women) feel that predestination has forced upon them. Electricity makes no fuss, leaves no puckered scars, sheds no blood, and can't exhibit the "specimens" to the gaping public in the doctor's sanctum, but I believe that in selected cases it will annihilate functional activity in these pestiferous organs which have mysteriously bothered women for a few years past. Let me illustrate.

In the last twenty years I have treated with localized electricity in its three forms a little over eleven hundred cases of ovarian neuralgia, or of general nervous disturbance believed to be dependent on ovarian congestion or inflammation, with or without associated uterine disease. Although I sometimes employed Faradism and static electricity, the great majority were treated by galvanism, and rarely with currents of more than fifty milliamperes. In some as much as two hundred milliamperes were used, and a profound impression of course resulted. I reported a few of my earlier cases, but as professional attention was not directed to electrolysis at the time, I ceased doing so. At a meeting of the Philadelphia County Medical Society ten or twelve years ago, the late eminent gynæcologist Dr. Albert H. Smith, condemned my use of from one hundred to two hundred milliamperes intra-uterine, and he was supported by others in his remarks, who, from all I can learn, never owned anything beyond a cheap Faradic machine either then or now. The three cases reported then as cured of membranous dysmenorrhœa and menorrhagia were (unknown to him) women who were unrelieved by his services, yet they remain cured to-day by my unwarrantable and inexpensive treatment. Apostoli wasn't around then.

1. In a case of extra-uterine pregnancy treated by high Faradic tension,[1] together with galvanism, the patient had given birth previously to three children, but since the electrolysis ovulation is apparently suspended or abolished; I believe it is destroyed. From a previous menorrhagic habit she is now scanty in her flow, and she wants fifteen years, at least, before the menopause is due. I sent a current of three hundred milliamperes through her ovaries twice for ten minutes, and a Faradic secondary of 7″–12″, first on one side and then on the other, for an hour, several times. The current traverses the uterus, the tubes, and the ovaries, in all applications. A complication which for nearly three years thereafter worried her and myself, was peristent chronic diarrhœa due, I feared, to paralysis of the intestinal muscular fibre from diffused currents. It was impossible to prevent this side-escape, or to isolate the pelvic nerve-trunks, hence I supposed the diarrhœa due to molecular destruction of portions of either tissue. Now I know better—it was masked intermittent, and was cured by arsenic and opium in very small doses, after failure of every known astringent or remedy against diarrhœa, suggested by professional friends.

2. Another case was that of a woman with chronic ovarian congestion, and in her I used Faradism to her utmost ability to stand it. The rheophores were applied, one over the glands singly, and the other in the uterus. After half a dozen seances her malady quit, and her health returned. She is only twenty-two, but she has ceased menstruating for two years. Her general health is exhuberantly perfect.

3. Again, another ovaralgia case, treated by galvanism and Faradism. Six weeks of moderate electric treatment was negative, and as she was a personal friend, as well as my patient, I was desirous of curing her; hence, I increased the doses to the utmost capacity bearable without anæsthesia. A few applications relieved her for a year, and on a threatened return I gave her a single

[1] *Medical Bulletin*, May, 1885.

dose of two hundred and seventy-five milliamperes, followed next day by Faradism up to 12″. She dropped her ovaralgia, and her ovulation also, I think. At any rate, she used to suffer for three or four days after menstruation ceased from pain, which stopped when accompanied by a little hæmorrhœa lasting only an hour. Her periods now are also scanty, short and painless; she has no secondary discharge. I believe ovulation occurred under the last flow, (that lasting an hour or so), and she is now sterile, or has been for several years. She was productive before the electrolysis.

4. The last case referred to is that of a woman presumably suffering from incipient cystic ovarian disease. Tumor was hereditary in her family, and she dreaded ovariotomy. I used strong electrolysis twice weekly for three months, and the swelling disappeared. So did ovulation, I am sure, although she menstruates regularly but scantily, when compared with her usual manner prior to the feared cystic development. She conceived and aborted three or four times a year before the electrical treatment—now she is barren, for there is no lack of trying to be a mother and her husband is all right.

If electrolysis did not destroy ovarian function in these cases, how can the subsequent history of apparent sterility be explained? That weaker currents than such as were used by me in the cases instanced will disorganize ovarian tissue, in recent specimens I know from abundant experiment. Why, therefore, should not very powerful currents do so in the living subject? Improper electrical treatment has utterly ruined many cases of paralysis, both infantile and in the adult, as every neurologist can testify; and electrolysis long continued will destroy the function of both nerve and muscle—why won't it do so in ovarian stroma?

The only question as I see it is the selection of cases, the method of application, and the attention due to the safety of the woman. I don't like a big abdominal poultice for the positive even if it is Apostoli*cal*. I prefer a well localized cataphoric rheophore not over two inches in diameter. It won't produce sloughs with care under galvanism, and Faradism won't do harm anyhow. There is more skill required in applying the vaginal rheophore, which must have a bare ball or disk. We can alter its position considerably from time to time, yet reach the ovary. I mean to try electrolysis for the purpose indicated hereafter, and I shall report the result. If electro-therapeutists will also experiment a little, something may come of it.

ON THE IMPORTANCE OF PRIMARY SUTURE OF DIVIDED NERVES, WITH AN ILLUSTRATIVE CASE OF SUCCESSFUL SUTURE OF THE MEDIAN AND ULNAR NERVE.[1]

BY CHARLES B. NANCREDE, M.D.,

SURGEON TO THE JEFFRESON MEDICAL COLLEGE HOSPITAL AND TO THE EPISCOPAL HOSPITAL, PHILADELPHIA.

Although I have a most profound faith in the vis medicatrix naturæ, I still think that Dame Nature should always have fair play in her battle with injury or disease, and this she certainly fails to receive at the hands of too many practitioners. In a paper published some fifteen years ago, I contended that, if with such vascular structures as those of the face, which certainly would unite sooner or later in some sort of fashion, we habitually resorted to suture, merely for cosmetic effects, we were all the more bound to do so for such vascular structures as tendons, which, if they failed to heal well, much more if no union was secured, must entail disability or total uselessness of a member. Nowadays a surgeon who should fail to suture a divided tendon would be considered derelict in his duties. In like manner, I trust, that in the near future the general practitioner will be so impressed with its importance that he will consider that his duty is unfulfilled until he, or some surgeon summoned by him, has sutured any divided nerve. It is needless for me to dilate upon the evils consequent upon the abolition of function of an important nerve, but I would recall to your minds cases which must have occurred in the practice of most of those present, where divisions of even such small trunks as digital nerves have resulted in troublesome ulcerations, causalgias, etc.

Doubtless the indifference of practitioners to wounds of nerves, or, more strictly speaking, their inclination to "leave them to Nature," has arisen from two causes, viz., (1) the fear that suturing might in some way determine tetanus, and (2) the well-known fact that nerves divided or even excised with the avowed intention of abrogating their function, too commonly reunite. The first cause should not deter us, as we now know that a suture, *per se*, can never originate tetanus; while as to the second objection, certain facts which I shall submit for your consideration warrant the conclusion that traumatic divisions of nerves, unless effected

[1] Read at the meeting of the Philadelphia County Medical Society, March 14, 1888.

by a clean cut—or perhaps ball wounds—involving solely the nerve and little, if any, of the contiguous structure, differ so materially from those purposely effected by the surgeon's knife, that conclusions derived from the result of neurectomies cannot safely be applied to accidental divisions of nerves. Besides, granting that reunion will occur without suturing, as a stitch can do no harm, why not use one, since it will at least conduce to a more rapid resumption of function? While primary union of nerves with immediate resumption of function—*i. e.*, in a week or ten days, is a surgical rarity, yet it does at times occur, and would doubtless be of more frequent occurrence, if suture were the rule and not the exception.

My aim in this brief note is merely to call your attention, as general practitioners in whose hands many of these cases will fall, to the *duty* of suturing divided nerves as a routine practice, just as you would tie arteries, and to describe a simple, effective method of carrying out the indication. A critical examination of the histories of nearly all exsections of nerves where reproduction has occurred, will show that they were removed either from a bony canal or from an intermuscular space in which they normally laid, *with the minimum* of injury to the surrounding tissues. Moreover, even when their ends have been turned back and sutured in position, or even buried in the surrounding tissues, they have been so secured in the same intermuscular space which the nerve normally traverses. In other words, the bony canals and the intermuscular spaces likewise, act as moulds which direct the course of the reparative material from the proximal to the distal end of the severed nerve. In extensive wounds, however, this condition does not obtain. Intermuscular spaces are dislocated, large masses of scar tissue are formed, so that instead of the new nerve-tissue being *compelled* to grow in only one, and that the right direction, it has too often an insuperable barrier interposed, and union fails.

In the case which I now show you,[1] the proximal ends of the ulnar and median nerves were directed at right angles to their intermuscular space, and would have been infallibly fixed between the ends of the torn muscles in a dense mass of scar tissues, resulting in permanent loss of power of the member. In the seventh month after suture, *i. e.*, the usual period required for the degeneration and regeneration of a nerve, first sensation, and then motion returned, until now, although the functions of the member are not perfect, the boy can earn his living, and do nearly all that can be effected by a normal hand and forearm.

Further quotation of my own cases or those of other surgeons seems hardly necessary, and such good results as I here show you have been frequently reported.

Finally, how should the sutures be passed and what should their material be?

Fine aseptic catgut passed by means of an ordinary sewing needle is to be preferred, but fine aseptic silk can be used, and I myself have resorted to this in an emergency. Should the nerve be *very* much lacerated and frayed out, it may, perhaps, be sometimes proper to cut off a portion to gain a clean surface, but this is rarely desirable. The needle should be passed from below upward through the proximal end of the nerve at one border, across and then passed from above downward near the opposite border, entering the needle from an eighth to a quarter of an inch from the cut end, according to the size of the nerve. The needle must now be passed from below upward through the distal portion of the nerve at the border corresponding to the last passage of the needle through the proximal end, across, and made to pierce the nerve from above downward, when the suture will be found to correspond to the free end of the thread in the proximal piece of nerve.

Gentle traction with an appropriate position of the member will, by the tying of one knot, accurately approximate the nerve ends. In a word, by this simple method all the advantages of the two separate sutures commonly recommended are obtained with a far greater degree of security. I need not say that the strictest asepsis should be secured, which is easy enough, provided the wounded part, the surgeon's hands, and his instruments be strictly cleansed, and the wound be freely irrigated with the bichloride and tartaric acid solution. If the surgeon gets an uncontaminated wound, it is his own fault if he has suppuration, and even with the ordinary run of accidental wounds, if he will thoroughly scrub his hands with a nail-brush and hot water, and likewise so treat the parts surrounding the the wound, pour boiling water over his instruments, without any fur-

[1] In this patient the brachial artery was also torn through, leaving only a bridge of muscle and skin through which collateral circulation could be carried on. The deficient blood supply possibly explains the failure of the recovery of power in the interossei muscles, although other of the intrinsic muscles of the hand which are supplied by the ulnar nerve contract well.

ther antisepsis, in most cases healing without suppuration can be secured, while the omission of these details will mar results with gallons of mercuric solution flowing over the wound.

JABORANDI IN OBSTETRIC PRACTICE.

BY JEROME HARDCASTLE, M.D.,
CECILTON, MD.

Having for many years noted the fact that parturition does not progress favorably till *diaphoresis* occurs, I have for some months past induced this condition, in the early stage of labor by giving fl. ext. jaborandi (*green*—the brown has proved worthless in my hands). My plan is, when called to a case, to order a warm brick to be applied to the feet—which are always cold, and then to give one-third of a teaspoonful of fl. ext. jaborandi in half a wineglassful of water, and repeat the dose every half-hour until perspiration occurs. It is very seldom that more than two doses are required. The first effect of this medicine on the patient is soothing, she becomes more quiet, and bears her pains with resignation. Upon being questioned the patient often states that her pains do not hurt her as they did. On examination, after diaphoresis occurs, the os will be found dilating rapidly; the soft parts to be in a favorable condition; and in a short time the labor will be satisfactorily terminated. Should the patient appear weak from the sweating, I wipe her face and neck with a dry towel, and give her a teaspoonful of whiskey or half as much of aromatic spirits of ammonia.

Since using the above remedy, I have had no occasion to use ether, chloroform, or the forceps. I have not seen any mention of the use of jaborandi in obstetric practice; but, having had such favorable results from its employment I recommend it to the consideration of the profession.

—The *Engineering and Building Record* of March 3, 1888, says: The Directors of the Great Northern Railway have recently issued an order to their firemen and engine-drivers which should be the imitation of similar regulations throughout the various railways in the country. No fireman or engine-driver is to be allowed to go on duty unless he has had at least nine hours' rest. Such an instruction should not be necessary, but being necessary, its issuance is no less a boon to the men than a source of safety to the public.

Society Reports.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Stated Meeting, March 7, 1888.

The President, S. Weir Mitchell, M.D., in the chair.

In opening the discussion on Dr. Ashhurst's paper[1] Dr. William Hunt said: Dr. Ashhurst has dwelt upon the importance of saving time. There is one way in which time might be saved, and that is by more than one surgeon operating at the same time. Dr. Morton and I have done that on two occasions, each taking a limb and operating at the same time. I do not know how it would work with three.

Dr. H. C. Wood said: I should like to make a remark with reference to this point of keeping up the animal heat. Many people die in acute disease, in acute poisoning, and after severe operations, because the temperature is not maintained. I have proven by experiment that if two animals are subjected to severe injury, and one is kept in a moderately cool room, and the other in a hot room, the one will die and the other recover. In this connection I will repeat a suggestion made to me by Dr. Dercum, which would afford one of the most efficient measures for maintaining temperature—and that is, to fill the ordinary water-bed with hot water, and allow the patient to lie on it.

Dr. Carr, of Washington, said: I did not know until I heard the remarks of Dr. Ashhurst the importance of a case that I have had. I have performed a quadruple amputation for frost-bite. The patient was brought into the hospital in a condition of collapse with the four extremities frozen. He reacted well, and remained in the hospital a week, when his constitutional condition became serious, and after consultation it was decided that amputation of the four extremities was desirable. I operated, removing one foot above the ankle, the other foot through the metatarsal joint, one forearm about its middle, and one hand, leaving a small stump of the thumb, disarticulating it at the metacarpophalangeal articulation. The patient did very well.

In operating I secured the vessels with hæmostatic forceps, and left the stump in that condition while I proceeded to amputate another limb.

[1] See page 423.

Dr. J. William White said: I understood from Dr. Ashhurst's paper that in his classification of triple amputations partial amputations were not included. I had last year at the University Hospital a double knee-joint amputation, with amputation of a portion of one hand, leaving a thumb and one finger, and should have been glad to present the patient this evening.

In reference to the technique, I have only one or two suggestions to make. If the irrigation is done with warm or hot water, it does not necessarily reduce the temperature, and, in fact, may aid in keeping up the bodily heat. The same is true with reference to the use of wet towels, which can be rung out of hot water and frequently renewed. Bramann, assistant to von Bergmann, has recently detailed the results obtained at the latter's clinic by packing wounds with iodoform gauze. This prevents the formation of a blood-clot, which is, perhaps, next to a failure to secure asepsis, the most important cause of the failure to obtain primary union. Where there is danger of oozing, he packs the wound with iodoform gauze, which is allowed to remain from forty-eight to seventy-two hours. It is then removed and the sutures applied; in the vast majority of cases union by first intention is secured. Even when it was left *in situ* for from four to six days such union occurred after suturing. In a case of double or triple amputation time might be saved by packing the first operative wound with iodoform gauze as soon as the vessels are secured, and then dressing it. This could be done by an assistant, and the patient removed to the ward much sooner than if time were taken to introduce stitches. The suturing could be done any time during the next two or three days.

Dr. Mitchell said: I have listened with a great deal of pleasure to the remarks as to temperature of patients under ether or chloroform, and the possible influence of irrigation upon these cases.

I would like to ask what some of the gynecological operators would say. In their cases the abdomen is sometimes largely opened, and the intestines exposed; if irrigation lowers the temperature in ordinary surgical cases, how much more should it do so in these?

I think it would be advisable to have a series of experiments and observations as to the effects of ether, chloroform, and perhaps other anæsthetics, upon the temperature, when used for long periods. As concerns the interesting case of triple amputation shown us by Prof. Ashhurst, I would like to say that no physiological statement has been made, so far as I know, as to the effect of large losses of tissue upon the pulse, temperature, nutrition, blood-pressure, amount of urine, etc. A tempting subject here awaits some industrious observer.

Dr. White said: Experiments are now being made at the University of Pennsylvania, upon animals and clinical subjects, to determine the effect of the administration of ether on the bodily temperature, and seem clearly to indicate that a drop of from one to three degrees may be expected, not only in cases where no irrigation was used, but even where no operation of any sort has been performed.

The note of a case has just been handed to me, in which the temperature fell four degrees. The temperature before operation was 99.5°, and after operation (which was the removal of a tubercular testicle) it was 95.5°. No irrigation was employed. No general symptoms of shock, such as weakness or failure of the pulse, leakage of the skin, or shallowness of respiration, were observed in this case. A series of nine cases of all sorts of operations gave similar results, though the average reduction of temperature was not more than two or three degrees.

Dr. William Goodell said: In removing the ovaries, one has to be very cautious on account of the collapse that may occur if the ovary is pinched or roughly handled. Something similar, I fancy, would occur in the removal of the testicle, and this, I think, had a good deal to do with the fall of the temperature noted.

Dr. Ashhurst said: The suggestion made by Dr. Hunt is an old one. Before the days of anæsthesia it was thought that the patient might suffer less pain by having both operations done at once; but when the patient is insensible, there will certainly be less confusion by having only one done at a time.

With reference to irrigation, as I have already mentioned, I have seen the temperafall as low as 97° after a simple operation, and in operations not usually considered capital, such as the removal of the breast, the temperature has gone even lower, and the patient has remained in an extremely critical condition for hours. This has been where there has been no loss of blood, and no condition other than the irrigation to account for it. In cases where antiseptic measures have not been employed, I have not seen this depression, except when there has been great loss of blood, or unnecessary exposure of the patient.

In my list I have not included any but synchronous major operations. The cases

reported to-night seem to have been instances of minor amputation, as regards some of the parts removed, and can, therefore, technically be looked upon as only double, not triple, or quadruple amputations.

Another word with reference to irrigation; even if warm solutions be employed, they will tend to cool the body by evaporation, and the same is true with regard to wet towels; even if hot when applied, they will reduce the temperature unless covered with oiled silk to prevent evaporation. I do not think that the administration of ether alone has much effect upon the temperature, but under any circumstances we can better dispense with irrigation and wet towels than with anæsthetics.

In regard to the case of excision of the testis, which has been mentioned, it may be said that operations on the testicle necessarily require considerable exposure of the lower part of the abdomen. It is also a well-known fact, that division of the chord is often followed by profound shock. This observation has been made by Mr. Erichsen, at the University College Hospital, London, and my own experience confirms it. The moment that the chord is divided, the pulse fails decidedly, and there is more shock from removal of the testicle than from any other operation of equal gravity in the whole range of surgery.

I have no objections to the antiseptic method of treatment, and I am in the habit of employing it, but I think that we should not close our eyes to the fact that it may have some disadvantages. I think that the maintenance of the patient's temperature is of more importance than the exclusion of a few microbes. All that can be accomplished by irrigation can be equally accomplished by washing the part before and after the operation, care being taken to keep the patient warm and dry. The ordinary antiseptic dressings were employed in this case after the operations; I consider that their chief advantage is that they permit infrequent dressing of the wound.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 15, 1888.

The President, A. Jacobi, M.D., in the chair.

Dr. F. R. Sturgis read a paper

On Some Questions in Connection with Syphilis Hereditaria Tarda.

It was only within the past twenty-five years, he said, that many diseased conditions had been ascribed to their true cause, namely, hereditary syphilis. The question which he wished to discuss was whether hereditary syphilis might lie dormant in the system, and first declare itself several years after birth. It was pretty generally acknowledged at the present day that if a patient presented himself to the surgeon with the advanced lesions of syphilis that the patient had had other and milder manifestations of the disease at some prior time. Surgeons went further and stated that the disease must have begun with an initial lesion, although no traces of it could be discovered.

Tables were given to show that in the majority of cases hereditary syphilis showed itself before the third month of life; but it was said that there were cases in which symptoms did not become manifest until later, and then the question arose, how much later?

Here Dr. Sturgis gave a brief account of cases reported by different observers who had asserted the occurrence of the first symptoms of hereditary syphilis at the twelfth to the twenty-seventh month, and in three cases from the twelfth to the fifteenth year. Comparing the histories of these cases with that of the usual history of hereditary syphilis, it would be seen that there was liability to mistake acquired syphilis for the hereditary form, and to overlook earlier symptoms of the latter disease. In the three cases quoted in which the symptoms of syphilis appeared at or after the twelfth year, Dr. Sturgis thought acquired syphilis could not be excluded. In the other cases early symptoms may have been mild, and therefore may have been overlooked. It was his own opinion that late symptoms of the hereditary form were always preceded by early symptoms, although the physician might be unable to draw out a history of the latter from the patient's relatives and friends. Sometimes it left the remains of an old keratitis, of mucous patches, etc.

Dr. E. L. Keyes thought late symptoms of hereditary syphilis were always preceded by early ones which had been overlooked or forgotten. Incidentally in the discussion he expressed the view that syphilis was a much more serious disease in children than in old people, because of the difference in soil; also that bichloride of mercury should be administered to young infants who had hereditary syphilis, say in one-fiftieth of a grain doses every two hours at first, and, as the symptoms began to yield, at longer intervals.

Dr. P. A. Morrow would be very much inclined to doubt whether any patient manifesting late evidences of hereditary syphilis had entirely escaped the early symptoms. He

had seen cases in which he had been unable to trace the history of early symptoms; but he did not regard that fact as at all conclusive that the early symptoms had not existed.

There was a disposition, he thought, to underrate the liability to lesions of hereditary syphilis after adolescence. We know patients might manifest acquired syphilis five or fifty years after taking it, yet hereditary syphilis was essentially the same disease.

Dr. R. W. Taylor said that while he looked upon hereditary syphilis as more erratic than the acquired variety, yet he was a firm believer that in the hereditary form there was always some manifestation in early infancy. If it could not be traced, it was because there were no remains of old lesions, want of persistence on the part of the surgeon in bringing out the history, or the ignorance of the patient and his friends.

Regarding lesions of hereditary syphilis after adolescence, he did not doubt but what they might occur, but he still claimed, as he had done in his chapter on this subject in Bumstead and Taylor's book, that after the twenty-first year it was extremely difficult to definitely exclude acquired syphilis, and unless strict precautions were enforced, physicians would be likely to attribute lesions to hereditary syphilis in many cases in which hereditary syphilis was not at all at fault.

Regarding the syphilis of old people being a light affair, as claimed by his friend Dr. Keyes, the statement was to him astonishing; for he had found that if there was ever a scourge to old people, it was syphilis.

Drs. L. B. Bangs, H. D. Chapin, A. S. Hunter, L. E. Holt, Goodwillie, and the President participated in the discussion. The general view was that late lesions of syphilis had been preceded by early ones, although the history might not be traceable.

SECTION IN PRACTICE.

Stated Meeting, March 20, 1888.

R. C. M. Page, M.D., Chairman.

Dr. J. West Roosevelt read a paper on

Pernicious Anæmia: Certain Questions Suggested by Cases and Autopsies.

From the study of certain cases of pernicious anæmia which had come under his observation and of reported cases he had been led to the following conclusions: (1) That in some cases of pernicious anæmia there is found a lesion of some important organs which, in certain cases, may have produced the blood disease. (2) That after these cases, together with those which seem to be caused by parasites and those which follow hemorrhage have been excluded, there remain some in which the blood lesion seems to be primary.

The first case related was that of a girl 20 years old, who had indulged in a peculiar and bad diet, and had taken much tea. She was at the age when simple anæmia is common. For a year she had menstruated irregularly, but she dated the real beginning of her illness from the period at which menstruation ceased, four months before admission to the hospital. Two months before admission she observed that she was paler than before, and she had occasional œdema of the feet. She did not seem to have been ill, however, until after an attack of jaundice one month before Dr. Roosevelt saw her. Following this and two similar attacks the graver symptoms appeared. Although she had temporary improvements she finally died, having presented the usual symptoms of pernicious anæmia. Dr. Roosevelt thought it might be assumed from the autopsy that the jaundice was the result of inflammation of the bile ducts produced by calculi found in the gall bladder. According to the patient's own statement the disease terminated fatally about eight months after its onset. As menstruation had been irregular for a year it was probable she had suffered from anæmia at least that long before admission. Taking into account the patient's age and her diet he thought it possible that the disorder began as a simple anæmia, and that the attack of jaundice still further increased the anæmia. As a result of the jaundice the blood-forming organs were taxed beyond their powers. Jaundice had been noted in several cases of pernicious anæmia.

The second case gave a very different history. There had been chronic gastritis extending over six months at least. Emaciation was a prominent symptom. The only apparent reason for the anæmia, besides the stomach lesion, was the occurrence of severe bleeding from piles thirteen years before the patient's admission. In spite of the emaciation the case resembled very closely pernicious anæmia. The autopsy showed the lesions of chronic gastritis. There was a question whether chronic diffuse nephritis was present, but the author was disposed to think the kidney changes were those of natural increase of fibrous tissue found usually in patients of her age. Of the relations between the stomach lesion and the symptoms this much alone could be said, that many patients lived a good while and pretty com-

fortably with a stomach as bad as this one. When this patient became very ill she presented symptoms like those produced by malignant disease. These symptoms were rationally explained by the blood state. It is possible that the blood state was secondary to the stomach lesion, but we would have to admit, for the production of pernicious anæmia as the result of gastritis, the necessity either of independent disease of the blood forming organs, or that as the result of the stomach lesion such a change took place in the gastric ferments as to lead to the production of poisonous digestive products instead of normal peptones. Evidence that the stomach and blood lesion were both the result of the same cause is wanting. It is interesting to note that in a number of reported cases symptoms of dyspepsia had preceded the anæmia.

In a third case of which the author gave a detailed history there was a condition of pernicious anæmia complicating Bright's disease. The patient died thirty-one days from the commencement of his blood lesions and hemorrhages from the rectum and mouth. Of course, said the author, the occurrence of symptoms of pernicious anæmia during the course of Bright's disease is well known. The blood had not yet been sufficiently often examined, but the patients seem to suffer from the same symptoms as those of pernicious anæmia, and in this case the blood lesions were typical.

Dr. Roosevelt gave a brief general description of pernicious anæmia. The onset was usually gradual. Pallor was frequently the first symptom noted, and when the disease had become fairly developed it was frequently rather characteristic; the skin had a yellow, lustreless, white tint. Dyspnœa, cardiac palpitation, headache and symptoms of increasing weakness developed; sooner or later an irregular fever set in; there might be some dropsy; patients usually retained their fat, or it might increase; hemorrhage from various mucous membranes occurred in some cases; hemorrhage into the retina and chorid was almost invariably present. The red blood discs and hæmoglobin were below the normal; the reduction might reach one-sixth or one seventh the normal. The white blood cells were nearly normal in number. The red cells showed changes in size and shape, and it was said nucleated discs sometimes appeared.

In some cases death took place in a few weeks or months; in others, not for years. Temporary improvement followed by relapses was often seen. The diagnosis from simple anæmia was difficult, and sometimes perhaps impossible. There seemed to be no symptom nor group of symptoms found in the grave disease which were not found in the milder type. Of course, if by pernicious anæmia we meant necessarily fatal anæmia, we might wait until death or recovery cleared up the diagnosis. The resemblance of these cases to Addison's disease was quite marked, but in the latter disorder anæmia was not a necessary symptom. Whether or not it was closely related to Hodgkins' disease and to leucocythæmia is not yet quite settled. Clinically, Hodgkins' disease is differentiated by the lymphatic, splenic, or hepatic enlargements, while the excess of white cells distinguishes leucocythæmia from the others. As to lesions, the blood during life is paler and thinner than normal. The red discs are much diminished in number, perhaps fifteen or twenty per cent. of the usual number could be found. The discs are more or less altered in size and shape; the white cells relatively, but probably not absolutely, increased in number. In other organs the most common lesions seem to be fatty degeneration of the heart, liver and kidneys; similar degeneration of the great vessels had been found. Hemorrhagic extravasation into the retina and chorid is almost constantly found. Together with some optic neuro-retinitis, extravasations of blood elsewhere may occur. Inflammatory changes in any of the organs may occur as an incident of the disease. The serous cavities often contain an excess of blood. Gastric lesions, chronic diffuse nephritis, lesions of the pancreas, fatty changes in the liver, etc., have been described. Intestinal parasites are sometimes seen. The body is usually fat; the muscles and all the organs pale; the fat is often of a peculiar yellow.

The etiology is not clear. If overwork, bad food, foul air, pregnancy, gastritis, etc., etc., are, as has been suggested, causes of pernicious anæmia, the disorder should be very common instead of very rare.

Looking at pernicious anæmia as he had defined it, making the definition broader than many would admit, might we not say, he concludes:

1. That a condition with similar course and symptoms had been observed in cases with precedent grave stomach, kidney and liver lesions?

2. That in these cases, however, the condition was so rare as to make it difficult to suppose that under ordinary conditions the blood state could be the direct result of them?

3. That in all cases in which there had

been any other tangible cause this had hardly been sufficient of itself to produce the disorder? There was too much gastritis, Bright's disease and misery seen without such effect. The same was true of every other cause.

4. Let there be congenital or acquired weakness of blood forming organs and then, as various authors had suggested, it would be conceivable that by a "vicious circle" the condition might result.

5. That after all known possible causes had been excluded certain cases still remained.

Finally, he would direct attention to the fact that in many cases, whatever be the supposed cause, there was a history of long-continued gastro-intestinal disturbance before the onset of the pernicious symptoms. In view of this, was it not possible that some of the cases were the result of poisoning by substances produced in the gastro-intestinal tract? If there was such a possibility, should not efforts be directed toward clearing out this tract in all primary cases?

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, March 14, 1888.

The Vice-President, W. W. Keen, M.D., in the Chair.

In opening the discussion on Dr. Nancrede's paper, on the

Importance of Primary Suture of Divided Nerves, with an Illustrative Case of Suture of the Median and Ulnar Nerve,[1]

Dr. H. R. Wharton said: I have seen one or two cases of primary nerve-suture, though none in which the injuries were so extensive as in this interesting case of Dr. Nancrede's. The results in these cases were good. There is another point to be considered. Shall we attempt secondary suture of the nerves when this has been omitted in the first place? I am very decidedly of the opinion that this procedure should be adopted, for a number of cases have been reported of this character, in which the results have been at least good suture enough to make me feel that secondary should be attempted when there is any probability of restoration of the use of the injured part. I thoroughly agree with Dr. Nancrede as to the great importance of this subject.

Dr. John B. Roberts: The only case of nerve-suture I remember at present is one in my wards, in which the work had very properly been done by the resident immediately on the admission of the patient. It was a rather extensive incised wound of the leg, involving, I think, the musculo-cutaneous and anterior tibial nerves. The muscles and nerves were sutured and dressed antiseptically, and the results were good; though I did not follow the case after discharge so as to make an accurate report as to sensation. Dr. Nancrede has incidentally touched upon a point of great importance, that of teno-suture. It has been my misfortune to meet with quite a number of cases in which this had been neglected by the attendant called at the time of the accident. One of these recently seen was that of a man wounded in the forearm just above the wrist, and in the ring finger. There was loss of flexion of the finger, but it was hard to tell which of the wounds to reopen in order to come upon and suture the divided tendon. The family physician believed it to be the wrist; but after cutting down, I found the tendon here flaccid and intact. I then opened the finger-wound, and here found the tendon retracted into the sheath. I sutured, but did not get a good result, probably from the extent of dissection necessary to get at the tendon in the sheath, and the great mass of cicatricial tissue. However, I never hesitate to reopen healed or partially healed wounds to suture tendons when this very important measure has been neglected.

I have been glad to hear Dr. Nancrede say that with cleanliness of person and of instruments asepsis can be secured without chemical solutions. This is in marked contrast to one of my friends, a surgeon of prominence, who thinks that the employment of solutions renders care as to cleanliness unnecessary.

Dr. J. William White: I do not know whether Dr. Nancrede spoke of the resection of the crushed and bruised ends of the nerves or not. The general principles of nerve-suture are admitted by all surgeons, but the question of resecting lacerated or contused ends before suturing, or of allowing them to remain, is one that should be carefully considered in each case. On the one hand, by resection of any considerable portion we increase longitudinal tension, and make greater strain on the sutures; on the other, we run the risk of including in the stitches tissue too much damaged to recover itself. There is some difference of opinion as to the particular suture to be employed. I should think that the one proposed by Dr. Nancrede, as shown in his diagram, would be open to objection, if, as there apparently repre-

[1] See page 429.

sented, it interposes a foreign substances, the catgut thread, between the ends of the nerve; this, if not absorbed, as is sometimes the case even with the best catgut, is liable to be a constant source of irritation, and to prevent union. I prefer and employ a suture passing quite through the nerve above and below the point of union. Evidence, either clinical, or pathological, or experimental, as to the relative advantages of different sutures is desirable, but I do not know of any, and I did not understand Dr. Nancrede to say that there was such evidence.

The CHAIRMAN, DR. W. W. KEEN: There are two case I may briefly cite from my own experience in connection with the subject of our discussion:

1. A case of primary nerve-suture in a boy two years of age, with perfect recovery of motion and sensation. The case occurred ten years ago. The child, carrying a glass bottle, fell, and a fragment of glass divided the ulnar nerve and artery about an inch and a half above the wrist. The mother made compression with her thumb until I arrived, very soon after the accident. After ligaturing the artery, I examined the nerve and found that it had been divided. I had only my pocket-case containing coarse white silk and an ordinary needle. Not wishing to leave the coarse silk in the wound, particularly not in the nerve tissues, I debated as to the method of suture, and devised one which proved eminently satisfactory. Drawing the ends together closely with forceps, I passed a surgical pin obliquely through the two divisions, threw a loop of silk around the point of the pin (as in Simpson's method of acupressure), drew out the thread, passed it around the head of the pin, where it was secured. At the end of forty-eight hours the pin was removed. The thread was thus loosened and removed. Perfect union of the wound took place in a few days. There was no wasting of muscles, and motion was present after twenty-four hours. While the age of the child prevented exact observation as to the time at which sensation returned, at the end of forty-eight hours there was an exclamation of pain on pricking the little finger with a pin. I saw the father of the boy about a year ago, who told me that his son had perfect use of hand and fingers.

2. Extensive teno-suture, with quick union. A recent case shows the value of even a brief suture of tendons. A man twenty-five years of age was admitted into St. Mary's Hospital with complete severance of all the tendons of the forearm and of the sheath above the wrist. The resident sewed each tendon carefully. He had only Kocher catgut, which does not remain more than three to five days, and then closed the external wound and placed the hand in flexion on a splint. The man left without permission after a few days, and it seems removed the splint and tore out the sutures in the skin. He returned later with a gaping wound in the forearm, but on testing the fingers separately each finger and each joint was found to have perfect motion, showing that even this temporary apposition of the divided tendons had a perfect result. I should prefer for the purpose, however, either very fine silk, or, better, the ordinary chromicized catgut.

DR. NANCREDE: Dr. White has misunderstood me. There is nothing between the divided ends of the nerve. If he will examine the rough model which I pass around he will see that the nerve is securely and accurately coaptated by the suture. I have no distinct recollection of resecting the injured ends in this case, in fact, I am nearly certain that I did not. In some cases I have said it *might* be desirable, but I am dubious about it. In two other cases that I recall at this moment, I remember that I did not make any attempt of the kind, but brought the ends together as best I could. Referring to the incidental discussion, I am glad to hear that so many of our members always suture tendons. I make it a rule to suture nerves and tendons in every case, and generally obtain fair results.

DR. HOWARD F. HANSELL presented a patient with

Ectopia Lentis.

Clarence P., aged ten. This colored boy presents several deformities: A peculiar shape of head, deviation of spine, anterior curve of each tibia, and is more or less undeveloped. I have asked him to present himself before the Society in order that those members who may be interested may have the opportunity to see a case of "ectopia lentis," congenital upward displacement of each lens. The margins of the clear lenses may be distinctly seen about the centre of each pupil. The right lens is dislocated upward. The left, upward and outward. Each eye is highly myopic—*i. e.*, as seen through the lens, and hypermetropic as seen under the lens. The temporal side of each nerve shows a large patch of atrophic choroid—post-staphyloma. There is no coloboma of the iris or choroid. With the right eye the boy can read large print only when held two and a half inches from the eye in an upward and outward position. The left eye is useless.

Reports of Clinics.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

SURGICAL CLINIC—PROF. ASHHURST.

Triple Amputation —Recovery.[1]

The first patient is a young man, a Moor, who is almost ready to be discharged from the wards. He has been the subject of a triple amputation, rendered necessary by injuries which he received in a railroad accident. His right forearm and right leg were hopelessly crushed, and the left leg was completely torn off an inch or two above the ankle. When brought here he was, of course, in a state of shock, but as soon as sufficient reaction had been secured to render it permissible, the operation was begun. The site of the first amputation was through the lower third of the right thigh, the second through the middle third of the left leg, and the third just below the wrist of the right side. All three stumps are now completely closed, and the patient's condition is excellent. In addition to the injuries of his extremities which required amputation, there was a compound fracture of the skull (the frontal bone), without, however, much depression. There were several severe contused wounds of the scalp, and a number of others distributed over the remaining portions of the body, some of which gave rise to deep and extensive sloughs. Recoveries after such severe injuries as we have had here, are very rare. Success, I believe, depends not so much upon the care and skill displayed by the surgeon in operating, as upon the constitutional vigor and healthy condition of the patient. I have had but one other case of triple amputation; and, although the man lived for ten days following the operation, he finally succumbed to exhaustion, due, unquestionably, to visceral disease resulting from alcoholic excesses. This young man doubtless owes his life to his youth and healthy condition, and to his temperate mode of life before his accident.

In cases like this, were there is grave injury, I invariably begin the use of carbonate of ammonium immediately upon the completion of the operation. Depending upon the age and condition of the patient, I order from two to five grains every two hours or oftener. This drug serves a double purpose—it not only is a powerful and prompt cardiac stimulant, but it acts, also, by maintaining the fluidity of the blood and so diminishing the tendency to the formation of heart clot. This is the condition present in the cases which received from the older surgeons the name of "secondary shock." It may cause death by gradual failure of the circulation, or it may kill suddenly by embolism. It may be necessary, of course, to combine with the ammonia such other stimulants as whiskey and digitalis, and the bodily temperature must be maintained by the application of hot-water bags, etc.

[1] See page 423.

Resection of Inferior Dental Nerve for Neuralgia.

This woman, past middle age, has suffered during the last four years from neuralgia of the lower jaw. In search of relief, she has had on different occasions, several teeth removed, but when the last one was extracted, her suffering, instead of being lessened, was aggravated.

We find that the pain follows the course of the inferior dental nerve. This, you are aware, is a branch of the inferior maxillary division of the fifth nerve. It enters the lower maxilla at the dental foramen, passes downwards and forwards in the dental canal beneath the teeth, emerges at the mental foramen, and distributes its terminal filaments to the chin and lower lip. Many different remedies and plans of treatment have been tried in the endeavor to afford relief to this patient, but all have proved futile. There can be no impropriety, therefore, in resorting to excision of a portion of the painful nerve.

Neurotomy, or simple division of a nerve, is not to be recommended, because prompt reunion would be almost certain to follow, and so render the operation useless. Resection, or neurectomy, is necessary, and a considerable portion of the length of the nerve should be removed, the object being to delay reunion as long as possible or prevent it altogether.

The nerve can be readily reached at its point of entrance to the canal. A semi-circular flap is raised from over the angle of the jaw, and the outer wall of the dental canal removed with a small trephine. The exposed nerve-trunk is now raised from its bed and about three-quarters of an inch of its length is removed. I will control the bleeding from the artery in the canal by introducing a plug of catgut.[1]

Gelatinous Arthritis—Excision of Knee-joint.

This patient is 45 years of age. His left knee began troubling him more than five months ago. The joint now, as you see, is

[1] The patient did well after the operation, the neuralgic pain being instantly relieved.

much swollen, the leg is somewhat flexed upon the thigh, and we find on palpation that the swelling has a doughy, semi-fluctuating feel. There is already some dislocation of the tibia; the ligaments are relaxed, and permit an abnormal degree of lateral motion. From the fact that motion of the joint is productive of severe pain, we are led to suspect the involvement in the disease of the layer of bone immediately beneath the articular cartilage.

I need scarcely tell you that this is an example of that variety of joint disease, called gelatinous arthritis. In this form the synovial membrane is found in a pulpy or gelatinous condition, which almost invariably leads to destructive disorganization of the joint. As the disease progresses, the articular cartilages undergo an analogous change, and it finally reaches the bones, which become softened and carious. The symptoms of this peculiar form of disease, appropriately called "gelatinous arthritis," and which is rarely seen except in the knee and elbow, differ from those of ordinary arthritis in several particulars. The swelling is more diffused, and attended with comparatively slight fluctuation, being of a doughy and somewhat elastic type. The pain is not very well marked, and in the early stages is of a dull character, differing both from the acute pain of ordinary synovitis and from the jumping pain which attends exposure of the bone by ulcerating cartilage. There is little or no heat, and should the part be at first red, the surface soon looses its color, often becoming at last positively blanched—an appearance so characteristic as almost to justify the name of *white swelling*, formerly given to these cases. Another diagnostic point is the mobility of the joint, which often remains even when the disease has reached an advanced stage. In the instance before us the morbid process has progressed so far that spontaneous cure cannot be hoped for, and removal of the joint becomes imperative. The question, therefore, lies between excison and amputation, and, in chosing between these two operations, preference should always be given to excision, provided that the circumstances of the particular case admit of a choice. In this case the circumstances opposed to this operation are the man's age and the extensive implication in the disease of the bones and surrounding tissues. Either extreme of life is considered unfavorable to excision on account of the long period requisite for recovery after the operation. If the soft tissues around a diseased bone or joint be extensively implicated, the result of an excision is less apt to be satisfactory than when this is not the case, though the operation is not absolutely contra-indicated by such a condition.

This patient has left the final decision of the operation to be performed to me, and I shall begin, therefore, as though I contemplated excision only; but if, on thorough exploration, I find that disorganization has progressed so far as to render the success of this operation doubtful, I shall resort to amputation. Excision of the knee-joint may be performed in several ways, but those of most common adoption are by the H, the U, and the simple transverse incision. The last is, in my judgment, the best, and is the one I shall select here. [After opening the joint cavity and subjecting it to a careful examination, the operator felt justified in attempting to save the limb by excising the diseased structures. The patient did well after the operation, the wound rapidly healing.]

Foreign Correspondence.

NEWS FROM PARIS.

Académie de Médecine.

A number of corresponding members now in Paris for the Congress of Surgery were at the last meeting of the Académie. M. Koegel, of Strasburg, read a note upon arthrectomy as practiced by him for gangrene of the knee. The process by which M. Koegel has obtained such good results consists in opening the joint, cleaning out the synovial cavity and the tendons or bones attacked by gangrene, and after applying appropriate remedies, making the limbs immovable for some time by means of a salicylate of soda cast. The disease should, however, be treated immediately on its appearance.

M. Queirel, of Marseilles, had employed antipyrine in hypodermic injections, and with women, as an anæsthetic, to diminish or overcome altogether the pains of labor. This remedy gave great success in these cases.

M. Doyen, of Rheims, made known the result of his researches as to the relation existing between the three microbes, those of puerperal fever, erysipelas, and purulent infection. He is inclined to think that the different manifestations produced by these microbes depend principally on their age and development. They undergo evolutions which make it difficult to decide whether they belong to a single or to several species. These observations, taken with those which M. Bouchard recently gave to the Académie, tend to confirm the

opinion that the idea which supposes the species of the microbes depend upon their form, is an error. The same microbe may be found under all the known forms. That is to say, in infectious diseases, these elements, though able to propagate infection and act as a means of carrying poison, are only the agents of the cause of disease, and not the cause itself. They may become the cause, but only in a secondary way, by carrying the disease from one subject to another.

French Congress of Surgeons.

The third congress of surgeons in France has opened. In his inaugural address, Professor Verneuil dwelt on all that surgery in France had accomplished up to date, and he drew a parallel between the attacks of Dr. Billroth, the German surgeon, and the praises bestowed on the efforts and results of French surgery in all the works of the learned societies in every part of the world. M. Verneuil thus spoke: "Dr. Billroth, after most violently attacking, with evident incompetence, our illustrious Pasteur, deliberately and without any reason reproaches French surgery for not keeping pace with the immense progress in surgical science made in Germany and England. I admit that we can, and that we should, learn something of our rivals, but I contend that it should be on a footing of reciprocity. I do not think we have far to go to find, in the esteem of our foreign friends, ample compensation for Dr. Billroth's attacks; in my opinion, no one is less capable than our eminent colleague of appreciating the value of French surgery, for the simple reason that no one is more ignorant of it than himself. If proofs in support of my statement were wanting, I would point out that I seek with you in vain, in the tenth edition of Dr. Billroth's *General Pathology* as in its first, for the slightest mention of the best French labors." After reviewing all that has been accomplished since the last congress, Dr. Verneuil concluded as follows: "Let us give unreserved praise, gentlemen, to the popularization of surgery, so much in keeping with the humanitarian and disinterested spirit of our race. The spread of surgical research in a democratic spirit, without detracting from the merits of the great, will widen the opportunities of the more humble; and the time is not far distant, when enlightened minds, and skillful hands, will be found in the remotest corners of our land. If the French Surgical Congress is enabled to hasten so happy an event, then it will have deserved well of Science and of our Fatherland."

M. Ollier, of Lyons, treated cases of *Ankylosis of the Wrist by Resection*, which left full mobility of the wrist, while at the same time preserving its radial and cubital motor tendons, which were formerly sacrificed. The antiseptic arrangements adopted enabled the operations to be performed without danger. The first case operated on by Dr. Ollier, was that of a young woman, already suffering from a compound osseous ankylosis of the elbow. In this case he resected the carpus and a centimetre of the bones of the forearm, and enabled her to perform on the piano.

Concerning *Ablation of the Larynx*, Dr. Demons, of Bordeaux, says he has successfully performed the operation in the following manner: "I first of all made a transverse hypohyoidian incision, from the middle of which I carried a transverse incision down to a little above the wound left by tracheotomy. I then effected the vertical incision of the thyroid cartilage; a step of the greatest importance, as it enabled me to ascertain that the left side was affected. I consequently determined on total ablation, which was effected, leaving only the cricoid, which I leveled by merely extracting the upper part of its amentum. The operation lasted three-quarters of an hour, and was most successful, thanks to the Trendelenburg canula, to which I superadded an iodoform pad. The after-treatment was of the simplest."

Dr. Dupont, of Lausanne, stated that the danger in the foregoing operation lay in the admission of blood into the respiratory passages. This is obviated by the use of Trendelenburg's canula; the serious inconvenience of this instrument, however, is that a fit of coughing suffices to expel it. Dr. Dupont said he obtained the same result, in a simpler and safer manner, by separating the trachea from the œsophagus, and folding it down forward in the lower angle of the wound, and there fixing it by a suture. This new direction removes it from the axis of the lower extremity of the larynx; and, therefore, the blood flows back of it.

In the operation of ablation, Dr. Molliere, of Lyons, excised one-third of the posterior part of the larynx, and a great part of one of the vocal chords, which he afterwards sought to reconstitute by suture. He completed the operation by a suture of the epiglottis to the cutaneous wound, in order to prevent the passage of food into the larynx. Molliere is in accord with Dr. Demous in recommending his method of operation for well-defined cancer.

The conclusion to be drawn from a long discussion between Drs. Chauvel, Delorme,

Poncet, Reclus, Trélat, Labbé, Nimier, Verchère, Chavasse and Castex, that in gunshot *Wounds of the Intestine*, immediate action of the surgeon offers great chances of success; but that the conveyance of a wounded person, for even a short distance, seldom leaves any hope of averting danger.

Periscope.

The Vaginal Tampon and Its Use.

In an address before the Alumni Association of the Woman's Hospital, Dr. T. A. Emmet spoke of the use of the vaginal tampon in the treatment of certain effects following pelvic inflammations. In the course of his remarks, (*N. Y. Med. Journal*, February 18, 1888) he stated that hot water is invaluable in the treatment of all stages of inflammation involving the cellular or connective tissue of the pelvis, in lymphangitis, in phlebitis, and in the early stages of pelvic peritonitis. On the other hand, he thinks that the vaginal tampon has only been beneficial after all acute symptoms have subsided. If this one feature is not recognized as a cardinal point, the indiscriminate use of this means of treatment will always be attended by unsatisfactory results, and with much unnecessary suffering to the patient. The only cases in the treatment of which he has derived any special benefit from the use of the vaginal tampon have been those in which he has supposed the blood-vessels had degenerated into a varicose condition, and where this state of the veins has been brought about from the effects of local peritonitis with adhesions, from the loss of the connective tissue, and from injury where the fascia has been involved.

In using the tampon we must trust, he says, to the use of the thermometer to show the absence of an elevated temperature in the pelvis, and to the want of other symptoms indicative of existing inflammation. In the absence of other symptoms we must exclude to a great extent the presence of pain on pressure as an evidence of active inflammation, its chief value then being but an indication of the manner in which the tampon should be applied. He holds that the tampon acts mechanically, by compressing the dilated veins and by lifting the uterus to its natural position in the pelvis, so that the circulation between the arteries and veins may be equalized. He has found that by repeated trials that the best material for tampons is the cleanest quality of cotton wool as sold in the shops and put up in rolls. In preparing it he takes a number of pieces of cotton of about the width and thickness of four fingers. He then makes a ball of each by turning the four corners or edges together, and while grasping these he thoroughly smears the outer surface with vaseline. Each ball is then of about the size of an English walnut and keeps it shape as it is packed loosely into a tin box for use. It was found advisable to have these balls of cotton as nearly uniform as possible and of about the size indicated.

On beginning the operation it is sometimes necessary to place the patient on the knees and chest before the uterus can be replaced. Then several balls are to be introduced and placed at a point where the uterus can be held by means of the finger while the patient is turning upon her back. One ball of cotton after another should be placed in the vagina and passed closely along the index finger of the other hand, which is engaged in pressing back the perineum and in holding up the uterus, or that portion of the tampon already introduced.

If one part of the vagina is more sensitive than another we must learn, he says, to "humor" it, by making less direct pressure until tolerance becomes established. When the sensitiveness is situated in the neighborhood of one of the broad ligaments we must pack the cotton on the opposite side of the cervix to act as a crutch. If the inflammation is chiefly about the utero-sacral ligaments, it is easy to tampon so that the uterus will be lifted without making direct pressure. The tampon should be placed so as to make as little direct pressure to the left as possible along the course of the rectum. After the introduction of a sufficient amount of cotton we are to pass the index finger carefully over every portion, to be certain that it is uniformly placed and to smooth down the entire surface. When this "finishing off" is properly done it is possible, from the coherency of the cotton and vaseline, to pack but a portion of the vagina. It may be but the upper part, or to one side, and it is likely to remain in position.

"There are two practical points in the application which, if not carried out carefully, will cause all our efforts to miscarry. The first is to keep the uterus, throughout the whole course of treatment, as nearly as possible in its natural position and at the same plane in the pelvis. The other is to place the fresh tampon without delay after the other has been removed. I have been in the habit of renewing the tampon daily for the patients in my private hospital. But if it could be kept deodorized, the longer it remained undisturbed the more thoroughly

would both of these indications be met in practice."

"The best instrument for removing the cotton is a piece of whalebone with a rough screw cut in the end, a simple device for the application of which we are indebted to the late Dr. Sims. This is easily passed alongside of the finger and twisted into one portion after another. It is well to leave that part directly under the uterus until the last, so that the finger may be slipped beneath the cervix, at the proper moment, to hold it in place until the fresh tampon can be introduced. To facilitate this, everything should be prepared beforehand. It is very evident if the uterus is allowed to prolapse, that just in proportion as it does so the circulation must be disturbed, and that if there is any advantage to be gained from maintaining a steady and uniform pressure, it must be, as nearly as possible, a continuous one. Therefore there should be no unnecessary delay in returning the tampon, as the blood begins again to rapidly dilate the vessels as soon as the pressure is removed."

A serious drawback to the satisfactory progress to be gained by this mode of treatment, says Dr. Emmet, is the recurrence of the menstrual period, when the use of the tampon has to be discontinued. To obviate this, just before the period is expected he removes the tampon and immediately introduces one of the rubber rings of a sufficient size to admit of the introduction of the finger between it and the vaginal wall at any point. These rings are about three-quarters of an inch in diameter, and so long as the patient remains in the recumbent position their broad surface offers a fair substitute for the tampon both in exerting a direct pressure upon the larger vessels and by taking up the slack in pelvic tissues. As soon as the flow has ceased he has a large hot water vaginal injection administered and then employs the tampon as before in the continued treatment of the case.

Traumatic Aneurism of the Orbit.

In the *Bristol Medico-Chirurgical Journal*, December, 1887, A. W. Prichard reports the case of a boy ten years old who was looking through a key-hole on May 23, and while in this position had a piece of umbrella wire thrust into his eye by a boy on the other side of the door. The wire probably penetrated deep into the orbit by the inner side of the eye-ball. A small wound on the conjunctiva and some blood under it towards the inner side, were the most noticeable signs of the injury. A few hours afterwards there was considerable ecchymosis; the globe was almost fixed, moving from side to side only about one-eighth of an inch; this was the cause of double vision; but with that exception, the sight of the injured eye was unaffected. During the first fortnight the ecchymosis was the only symptom; both lids were very dark and the ocular conjunctiva had blood under it. The boy complained very little, and a cold pad was kept generally over the eye. By June 9, however, there was some protrusion noticed, and a faint pulsation could be felt on putting the hand over the eye-ball. On listening with a stethoscope on the eye, a loud bruit could be heard; this was audible all over that side, and faintly over the other side of the cranium. Moreover, the boy complained of a blowing sound in the left ear. Thinking the case was one of traumatic anuerism—or possible of a blood-tumor pressing on the carotid artery, the author for three weeks tried the effect of continuous pressure on the eye-ball with ice around the orbit. This had the effect of ameliorating the diplopia, but accurate measurement from the forehead proved that the protrusion of the globe was increasing.

By July 4 the protrusion had increased so that the injured eye was as much as $\frac{1}{16}$ of an inch in front of the other. There was considerable chemosis and blueness all round the orbit; the bruit was very marked, and pressure on the left carotid entirely stopped it; the boy had headaches and restless nights. Accordingly, after consultation, on July 5, he tied the common carotid on that side at the level of the cricoid cartilage. There was no great difficulty in the operation; the vein was large, and as it were enveloping the artery, and it had to be held carefully out of the way. The vessel was tied with medium-sized catgut, and a small drainage tube put in the wound; the operation was done without a spray. In the evening after the operation no bruit could be heard and no pulsation felt, and the eyeball had receded $\frac{1}{8}$ of an inch. During the next week the boy went on very well. The wound healed very kindly and the eye receded; the double vision was less, and the chemosis and swelling of tissues round the orbit went down. He remained in the infirmary for six weeks after, and to the author's disappointment the bruit returned, and was heard as early as one week after the operation. It was not nearly as loud, however, and was inaudible to the patient himself. The eyeball receded as gradually as it had come forward, and when the patient went out the protrusion only amounted to $\frac{3}{16}$ of an inch. The diplopia was still present, but in other respects the boy was well.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

THE TREATMENT OF INEVITABLE MISCARRIAGE.

Some authors divide the premature expulsion of the ovum into abortion, miscarriage and premature labor. While this is a purely arbitrary classification, it has the advantage of calling attention to the fact, that in general terms the immature ovum is cast off by one of three methods. First, the ovum is cast off entire, the decidua sometimes accompanying, and sometimes following it. Second, the membranes rupture, the fœtus is discharged, and the secundines follow with difficulty. Third, the conditions are analogous to those at term.

During the first two months, when the ovular attachments are slight, the ovum is usually expelled *en masse*, without difficulty, the decidua subsequently coming away in shreds or as an entire membrane. The physician is seldom called on to treat these cases, as the patient is apt to consider the hemorrhage as a delayed and somewhat difficult menstruation. The ovum is usually passed in enveloping clots, and frequently escapes attention. Sometimes the ovum, as well as the decidua, is discharged as detritus. The dangers here, as in all cases of miscarriage, are two—hemorrhage and sepsis. At this early time these are slight. Should serious hemorrhage occur and continue after the use of ergot and the tampon, the case should be treated like one of obstinate bleeding from the non-pregnant uterus, the cavity should be gently curetted with Thomas's curette, and either mopped dry with cotton on an applicator, or irrigated, and have Churchill's tincture of iodine thoroughly applied to its cavity. This application is not caustic, and it is both hæmostatic and antiseptic. Before the third month sepsis is hardly to be feared; it could scarcely be present except by direct infection from the examining finger of the attendant. If present, its treatment would not differ from that of the later months.

Frequently during the third month, more rarely afterward, the ovum is expelled entire. In this form of delivery the hemorrhage is slight, owing to the intra-uterine pressure of the intact ovum. Hence, if on making touch during the third and fourth months the elastic amniotic sac is felt, great care should be taken to avoid rupturing it. Should the ovum be found in the vagina or hanging free in the cervix, it should, of course, be removed. But detachment is a *sine qua non*. Before detachment, officious effort may rupture the membranes and add the greater dangers and difficulties of that form of delivery. Unless the patient be unusually distant from the attendant, with ordinary contraction no treatment is called for. But as the membranes are liable to rupture without warning, and hemorrhage to ensue, under peculiar circumstances a tampon may be introduced as a matter of precaution. Nevertheless, where the physician can visit the patient with reasonable frequency, it should not be used in this class of cases. It needlessly complicates the treatment, and unless strict antiseptic precautions be taken, it increases the liability to septicæmia. Besides, it adds to the discomfort of the patient. Where the process of expulsion is slow, it may be hastened by moderate doses of ergot, a half drachm of the fluid extract every third or fourth hour. The

Faradic current is also recommended to increase the force of the contractions (Grandin). A weak current should be used, one pole being held by the patient, the other passed over the hypgastrium. I have not used the method. The tampon may be used in tedious miscarriage, not for its hæmostatic powers, but for its reflex effect upon the uterine contractions.

When rupture of the membranes occurs, either from criminal operative measures, uterine contractions, or the manipulations of the attendant, two complications are apt to ensue: active hemorrhage, and retention of the secundines. With the collapse of the membranes intra-uterine pressure is reduced, and the ovum no longer acts as a natural tampon—hence the bleeding. The uterus also acts at a disadvantage, thus increasing the liability to retention. It is here that the tampon finds its strongest indication. It should be reinforced by the administration of ergot. All authors agree that to be effectual in restraining hemorrhage it must be well applied. Various materials, such as a sponge, a handkerchief, tow, cotton, wool, or a roller bandage have been recommended. Pledgets of the material selected may be introduced along two fingers as guide, or through a Ferguson's, a bi-valve or a Sims' speculum. The Sims' position and speculum unquestionably offer superior advantages, and should be selected, except under extreme emergency, when time may be all important. Cotton-wool pledgets should each have a string attached, or be made after the kite-tail principle, to facilitate removal. They should be squeezed out of carbolized glycerine and water (1–40). The antiseptic gauze roller-bandage can be substituted for the muslin "roller" recommended by Taylor. It has the advantage of being already prepared, and it is easy of introduction and removal. After irrigation of the vagina with an antiseptic solution, the patient should be put in Sims' position, the perineum retracted, and the tampon applied by packing first the posterior fornix, then the anterior, and last the vagina down to the outlet (the Sims' method.) This may be reinforced by a pad over the perineum and vulva, and a T bandage. After twelve hours the tampon should be removed, although Charpentier advises that it remain twenty-four or even thirty-six hours. Irrigation should always be practiced before touch, as the tampon, in spite of antiseptics, is apt to cause a foul smelling discharge. The fœtus (if not previously passed) and the fœtal envelopes are frequently removed with the tampon, or are found free in the vagina or cervix. Should retention still exist and the os be closed, the tampon should be reapplied. Should this be removed at the end of twelve hours and retention still exist, we are met with the problem as to whether we shall continue the ergot and tampon treatment, or clear out the uterus at once. According to Lusk, Mundé and Playfair, experience fully proves that where the neck is dilated or dilatable the uterine contents can be removed without danger; and the woman is forthwith protected against hemorrhage, and the dangers of sepsis are reduced to a minimum. The French, almost as a unit, and various other authorities, oppose active interference unless symptoms of sepsis or putrefaction occur. Then they interfere in the usual way.

We believe the best rule to be: if, after twenty-four or thirty-six hours' use of ergot and the tampon, the uterus is not empty: empty it. And with each additional experience the temptation grows stronger to follow the more extreme plan advocated by Lusk and others in these cases—to empty the uterus as soon as you can get a finger into it. If the cervix is not dilated, it may be dilated with hard rubber dilators or tents. Engelmann advises the use of slippery-elm tents. The finger is often the best dilator.

The method of emptying the uterus is not indifferent. The finger is necessarily the safest instrument of removal, as it alone is sensitive. Dull curettes of different sizes are safe and efficient in good hands. But a certain amount of experience is necessary to tell when the cavity is clear of the secundines. Lusk truly says that deliberation and perseverance are the main elements of success. Ether is always an assis-

tance, and is often necessary in nervous and primiparous cases. The patient should be placed across the bed, the hips well drawn to the edge; then the index finger is inserted, and made to pass up one side, across the fundus, and down the other side (the nail in contact with the uterine wall), separating the secundines in its progress. The other hand is made to assist by depressing the uterus from above. The *débris* should be removed as far as possible with the finger, and the remainder washed away with the irrigator. After this a fifty-grain iodoform pencil may be placed in the cavity.

From the fourth to the seventh months the fœtus is usually discharged after rupture of the membranes, the placenta and membranes following or being retained. After this time the process of delivery is similar to that at term. Rarely, the ovum is expelled entire. In such cases the treatment does not differ from that of similar cases in the third month. Interference is not usually demanded until rupture of the membranes. Expectancy should be practiced. After the discharge of the fœtus, which at this time necessitates a considerable amount of cervical dilatation, the way is open for the immediate removal of the placenta and membranes. Ergot and the tampon may be used in the fourth month, but after this the danger of concealed hemorrhage overbalances their advantages. The method of removal does not differ from that for the third month, except that we have more room as the pregnancy advances. During the fifth, sixth and seventh months, a modification of Crède's method at term will often succeed, not only in controlling hemorrhage temporarily, but in expelling the uterine contents.

In certain cases, in which the contents of the womb may or may not be considered to have been discharged, we are called upon to treat the consequences of retention. These are the "incomplete" and "neglected" cases. The patient complains of pains, hemorrhage or septic symptoms subsequent to a miscarriage. Where portions of placenta are retained, with sufficient vascular connection to maintain vitality, a polypoid mass results, with metrorrhagia. Where the vascular connections are less, more or less rapid decomposition ensues. The indication to clear out the uterus is the same in both. In the hæmorrhagic cases, ergot will often expel the mass, but the most certain, most surgical way is to dilate the cervix, and remove the mass with the finger, curette, or polypus forceps. The cervix in these cases is often closed, and for dilatation the Wilson steel dilator is the best. After removal of the polyp it is well to gently curette the cavity, and to apply Churchill's iodine. In the septic cases, with foul putrescent discharge, the os is generally open and dilatable. Here, also, the finger is the best implement, but in cases of difficulty there is danger of self-infection. This is an argument in favor of the curette, in these cases. After removal of the retained mass the uterus should be irrigated with hot bichloride solution (1–2000), and
form pencil, of fifty or one hundred grains, introduced. There is commonly a chill, with a sharp rise of temperature, even to 105° F., shortly after manipulation. This is due to increased absorption of septic matter, caused by the abrasions made during the removal of the uterine contents. Unless systemic infection is marked, rapid improvement follows. If otherwise, the treatment does not differ from that of septic infection from putrescent matter *in utero* at term.

It is scarcely necessary to insist, at this time, when the necessity and value of antiseptic precautions in labor are so fully recognized, that the same rigid exclusion of infectious material from the genitals is of great importance. Personal disinfection of the attendant, especially of the examining or operating finger or hand is the greatest desideratum.

OPERATIONS FOR ABSCESS IN THE BRAIN.

At a meeting of the Medical Society of London, March 5, 1888, Dr. Ferrier and Mr. Victor Horsley read the notes of a case of cerebral abscess associated with a discharge from the ear, in which Dr. Ferrier diagnosticated the presence of an abscess in the brain and Mr. Horsley operated successfully for its

evacuation. As there are but few such cases on record, this one is of peculiar interest. The patient was a man, 47 years old, who had been ill since November 10, 1887, and on the fifteenth had had an offensive discharge from the left ear. On December 8, when Dr. Ferrier first saw him, he was drowsy, and complained of pain on the left side of the head. He had no paralysis. His pulse was 52, weak and intermittent. His respirations were 14 to the minute, labored and sighing. His temperature was normal. After a temporary improvement, he was at the end of six days more drowsy, and in a few days more he developed some delirium and confusion in his speech. There was also some weakness of the right angle of the mouth.

On studying these symptoms Dr. Ferrier came to the conclusion that the man had an abscess of the brain, probably situated in the anterior part of the third left temporo-sphenoidal lobe, and abutting or pressing upon the fissure of Sylvius. Mr. Horsley agreed in this diagnosis, and, on December 9, he operated by trephining the skull, opening the dura mater, and puncturing the brain with a trochar. The result was the evacuation of about five fluid drachms of odorless pus. After this the patient went on uninterruptedly to recovery.

In commenting on this case Dr. Hughlings Jackson described the result as simply magnificent, and other members of the Society joined in his admiration of the acumen and skill displayed by Dr. Ferrier and Mr. Horsley. Similar feelings must be excited in the minds of all who learn its details; and no one can doubt that to these men the patient owes his escape from impending death.

Operations upon the brain are no longer novelties in surgical experience, and they have been brought into prominence especially by the work of certain German and English surgeons. Among the former, Krönlein stands pre-eminent; and among the latter, Horsley. For a correct appreciation of the indications for, and the technique of their performance one must have a knowledge of the anatomy and physiology of the brain, as well as of the phenomena dependent upon the various lesions of it, and some acquaintance with the details which have been better described by Wiesmann, of Zurich, in the *Deutsche Zeitschrift für Chirurgie*, 1885, than by any single writer with whose work we are familiar.

So far very little seems to have been done in this country in the way of operating upon intra-cranial abscesses or morbid growths, or for the relief of intra-cranial hemorrhage; but the time seems to be ripe for some evidence of the same skill in diagnosis and in operative action, which has of late shed so much lustre upon our brothers in Europe. We may be more fortunate than they are, in the apparent lack of opportunity for imitating their boldness; but it is not unlikely that a better knowledge of what may be known of and done for intra-cranial lesions would lead to the detection of opportunities which now go unrecognized.

SCOTCH OATS ESSENCE.

In the number of that outspoken journal, the *Boston Journal of Health*, for March, 1888, there is an article which discusses the character of so-called Scotch Oats Essence, and in which the statement is made that it contains about thirty-five per cent. of alcohol by measure. This statement is placed in contrast to that of the makers and advertisers of this preparation who assert that it is an absolutely harmless vegetable tonic, which will free the victim of the alcohol habit from his terrible bondage.

This interesting contribution to the literature of the Scotch Oats Essence has been followed up by an article in the *Druggists Circular* for April, in which the statement is made that this Oats Essence contains morphine. A careful quantitative analysis disclosed the fact that a bottle contained more than two grains of this alkaloid.

The information secured and published by the two journals mentioned is of great importance to all medical men; for it is not long since this special preparation was advertised in a large number of medical journals, and probably secured some recommendations from members of the medical

profession. At the present time the manufacturers are making continuous and strenuous efforts to secure a large sale for it, and they have not hesitated to proceed by methods which recently resulted in an action being brought against them for the misuse of the name of a well-known physician in New York. It is well, therefore, that medical men should be on their guard against this so-called tonic, and take pains that there shall be no doubt as to their attitude toward a preparation which is claimed to be absolutely harmless, and yet contains such considerable quantities of alcohol and morphine. It is time that physicians took a more active part in suppressing some of the frauds which, in the guise of medical treatment, are practiced on the community; and if the allegations in regard to Scotch Oats Essence are true, it is a first-rate fraud to begin on.

In this connection, we take pleasure in recommending to the appreciation and gratitude of our readers the two journals named above, which are doing such service in investigating and disclosing to the public the ingredients of a number of much-advertised nostrums. Such service is rarely rewarded as it deserves, but it shall not miss whatever recognition the REPORTER can give it.

ANTI-ADULTERATION BILL.

The United States Senate has just passed a bill, introduced by Mr. Edmunds, providing for an inspection of meats for exportation, and prohibiting the importation of adulterated articles of food or drink. It seems that this bill has been introduced and passed in order to give the President power to exercise the pressure of retaliation upon European countries which have excluded certain articles of food—notably pork—sent out from America, on the score of unwholesomeness, but perhaps really because they competed too strongly with products of their own peoples.

But whatever may have been the motive prompting the Senate, it is pleasant to note that a beginning has been made in this important matter. The present bill provides for a government inspector of meats designed for exportation, and forbids the importation into the United States of any adulterated food or liquors. It gives to the President ample power to enforce its provisions against any country from which adulterated articles are imported, and, if carefully carried out, cannot fail to prove of great advantage. It may, and we sincerely hope it will, prove but the beginning of broad and wise measures for the protection of the public health. If the Constitution of the United States does not justify the exercise of such a paternal authority in matters of health as is in force in less democratic countries, we trust that Congress may at least exercise the prerogative of initiating some general movement among the States, so that all over the country there shall be uniform laws protecting the public health.

PENNSYLVANIA STATE MEDICAL SOCIETY.

The time for the next meeting of the Medical Society of the State of Pennsylvania (June 5) is approaching, and it is desired that the programme shall be completed as soon as possible. For this reason, gentlemen who intend to read papers are urged to send their names and the titles of their papers at once to Dr. John H. Packard, of the Committee of Arrangements, 1924 Spruce street, Philadelphia. The time to which applications for a position on the programme is limited, is April 15.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the REPORTER.]

DISEASES OF THE SKIN. By JOHN V. SHOEMAKER, M.D., Professor of Skin and Venereal Diseases in the Medico-Chirurgical College of Philadelphia. New York: D. Appleton & Co.

Considering how little we have advanced in our knowledge of the etiology and pathology of the different skin diseases since the time of Hebra, it is somewhat astonishing to how many exponents in the form of manuals and text-books the intervening years have given birth. For so young a specialty its workers are apparently both numerous and zealous, although of late the most energy has been directed in therapeutic channels. The book before us is the third large octavo volume in this branch which has appeared in the past several months.

This treatise in its general arrangement and descriptions resembles closely those which have preceded it; in fact, its arrangement is almost identical

with that adopted by Duhring. In a few respects, the author swerves from the usual classification, evidently following in this respect "Robinson's Manual." Lichen planus and lichen ruber are considered, for alleged pathological reasons, as distinct diseases, and not as different phases of the same process as generally accepted. The first is placed under the inflammations, and the latter under hypertrophies. The correctness of this view, however, has been denied by other investigators. Psoriasis has been transferred from the inflammations to the hypertrophies. This tendency to reclassify, upon individual investigations alone, does more to mystify than to aid in the advancement of our knowledge. Classification depends upon the sum of our information, and although all data are valuable as tending toward a clear understanding, until more or less unanimity obtains a new departure is scarcely justifiable. In the present instance, therefore, the author does not carry out his intention as expressed in the preface "that the whole work has been written from the standpoint of an active general practitioner, and can hardly fail to bear that impress." The chief complaint of the general practitioners against dermatologists has been the incessant and confusing changes in the names and classification. It will be difficult to explain intelligibly to the general practitioner, with the inflammatory signs of psoriasis before him, that the disease is a hypertrophy, and it is only just to the general medical public to add that as yet such a view of the disease is far from accepted by the dermatological world. The author offsets this slip, however, in incorporating in the work a consideration of the cutaneous symptoms of the exanthemata. We believe that such should find a place in every text-book on diseases of the skin. No mention is made of the disease, or group of symptoms, known as dermatitis herpetiformis. Under this or another name these cases demand recognition.

So much has been written by Dr. Shoemaker in regard to the therapeutics of skin diseases, that naturally this part of the work was expected to be the strongest, but on the contrary it is disappointing, although in many respects original. The oleates are still in favor with him, although, with few exceptions, they have after trial failed to find a permanent place in the therapeutic resources of those specially engaged in dermatological practice. The author states his confidence in sulphur as one of the most valuable remedies in the external treatment of chronic eczema. This is contrary to general experience. It is true, it is useful in certain cases, but the number is extremely limited; in most instances it will be found to aggravate, and under all circumstances should be employed cautiously. On the other hand, the author refers but briefly and subordinately to the usefulness of sulphur and its preparations in acne and rosacea. In sycosis, also, the same remedy is scarcely mentioned, although beyond doubt, when judiciously prescribed, it is the most valuable in the whole list. In short, if we take him at his word, the author is able to cure his cases on lines of treatment quite different from those usually adopted by dermatologists.

The micro-photographs which accompany the text are excellent; the colored plates, with one or two exceptions, are simply atrocious. With this exception, the publishers' part of this book is well done.

—Numerous foot-ball accidents in the way of broken limbs are being reported by the English journals.

MODERN TREATMENT OF HEADACHES. By Allan McLane Hamilton, M.D. 5½ x 7 inches, pp. 124. Detroit: Geo. S. Davis, 1887. Price, 25 cents.

This book is the November number of the "Physicians' Leisure Library." It contains an excellent account of the different varieties of headaches and very valuable suggestions in regard to their treatment. The author sends it out with a modest preface; but we believe it is a book calculated to be of great service to every physician. We are glad to be able to speak more favorably of it than we have done of some of the numbers of this series, the design of which is good, whilst its execution has thus far been very unequal. We must, however, call attention to some defects which we presume are chargeable to the proof-reader; for we cannot believe, for example, that Dr. Hamilton would be guilty of the errors which are to be found in his prescriptions as printed in this book. These errors, it must be stated, do not affect the value of the formulæ, although they will offend those who respect accuracy of statement and correct spelling. The book is a good book, and may be safely recommended to our readers; but before it goes to a second edition the errors we refer to ought to be eliminated from it.

Pamphlet Notices.

Medical Organization. By A. N. Carrigan, M.D. From Transactions of the State Medical Society of Arkansas. 4 pp.

—Dr. Carrigan, who has died since he read this paper at the twelfth annual session of the Arkansas Medical Society, makes in it, an earnest plea for the formation and hearty support of county medical societies. These he regards as the starting-point for advancement in the republic of medicine, and as a great means of education and cultivation in the art of medicine.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—*Babyhood* for March continues the useful work which this magazine began about three years ago. It contains much valuable information for parents, especially mothers, and for intelligent nurses. By far the best part of this is that contained in the editorial departments, while the original articles are very good, even if some are a little too technical for the nursery.

—The *Boston Journal of Health* is a wide-awake, interesting and useful monthly, each number containing about sixteen large quarto pages. Subscription price, $1.00 a year. Just now it is exposing with great vigor the claims of a number of quack remedies. The number for February devoted considerable space to an analysis of what is known as "Murdock's Liquid Food," and the number for March follows this up with a refutation of what appears to be a rejoinder. This sort of thing makes interesting reading, and, we believe, is calculated to do much good.

Correspondence.

Prescribing Druggists.

Editor Med. and Surg. Reporter:

Sir:—Although not a doctor, nor even a "prescribing" druggist, I am a constant reader of the Reporter, and have been for a number of years. I have just read the tirade of B. P. Reese in the last issue, and wish to protest against his wholesale denunciation of druggists, because he has cause of complaint against a few black-sheep in the fold of pharmacy; I do not offer any excuses for, nor uphold "prescribing druggists." Like "rum" drug-stores, there is no excuse for them.

But who are the prescribing druggists? Nine out of every ten are like the particular one referred to by Dr. Reese, *i.e.*, M.D's. engaged in the drug business; not pharmacists, nor chemists, but simply doctors assuming a profession that they are not as capable of filling as the average pharmacist is of prescribing for a cough, cramp in the stomach, or other minor complaint. We would like the doctor to suggest some way to teach physicians "to confine *themselves* to their legitimate business," and stop the growing evil of overcrowding our business, or we will be compelled to get an M.D. diploma and practice medicine ourselves.

It is not a fact that "druggists do all in their power to deprive the physician of his fee." On the contrary, as a class, we are always willing and glad to extend to the physician such help and professional courtesy as we can. The M.D. druggists may, and do, absorb the total fees; but there is no way nor use of retaliating, as not many of them have much prescription business outside of their own practice, so that a "boycott" will not remedy the trouble.

Has a doctor, or anyone, a right to prescribe for a patient he has not seen or examined? Preferably not; yet observation shows that not less than half of the prescriptions for coughs and the minor ailments are written by physicians in good standing, on the word of another without seeing or examining the patient. Would you deprive your brother in the profession of the same privilege because he is engaged in the drug business?

Aside from ethics, there is a legitimate demand among the poor and those of limited means, who are not able to fee a doctor for every "grunt," for cheap remedies for those ailments, as evinced by the frequent calls for "a nickel's worth of hive-syrup, paregoric, Brown's mixture, etc.," and the number of "receipts for cough syrup" of domestic origin, as well as the demand for "patent medicines." Should not a pharmacist be as competent to prescribe a good cough syrup, or worm powder as a doctor who has not seen his patient, or the patent nostrum maker? This demand will always exist, and if not supplied by the druggist, it will be by the grocer or dry-goods man. You may legislate at it, and control it by inspection, as should be done with proprietary articles; but you can't stop it any more than you can prevent a mother from giving catnip tea or paregoric to a sick baby, or the mechanic from filling a fresh wound with tobacco juice.

There are just causes of complaint on both sides, and there is no use in denouncing your co-workers as a class because a few offend. "Let us have peace."

Yours truly,

Sharon, Pa., March 17, 1888. A. L. Beck, Ph. G.

A Physician's View.

Editor Med. and Surg. Reporter:

Sir:—I notice in the Reporter of March 10, an article from B. P. Reese, of Virginia, on the "Prescribing Druggist." This subject is one, owing to the crowded condition of the ranks, that should elicit the attention of the medical profession. It is very obvious that the druggists are, through this medium, annually taking many thousands of dollars that belong to the physicians. The notion of the people in going direct to the druggist to prescribe for their chronic aches and pains is truly an unnatural state of affairs. Nevertheless, custom has established this notion in the minds of one-half, if not more, of the people, and they do it, and will continue so to do, irregardless of all the laws the Legislature can pass. One-half, at least, of the people do not comprehend the value of a correct diagnosis, and they absolutely realize the fact that the physicians, as a rule, don't handle medicines, but only give prescriptions; consequently, as they don't place the proper value on advice and prescriptions, it is a minor matter with them; and with the view of saving the charges for such they go direct to the druggist, and leave the physician out of the deal, and it is not very often that the druggist sends them back to the physician; but he caters to please them, and that in his own interest, amply supplied with the remedies suited exactly to his own peculiar business, such as syr. hypophosphites, liquid lactopeptine, bromo-caffeine, and many others that could be mentioned,

and so moves the business. Now, the law to stop this resides within the medical profession, proper. Let each physician keep and compound his own remedies for his patrons, and the result will be: in place of the people going to the druggists, they will go to the physician; his office practice will be increased; it won't take the number of patrons that it does at present to support each physician; the people will be better satisfied; the dignity of the profession not a bit lowered, and its power to protect its own interest greatly increased.

Yours truly,

CHARLES W. MUSGROVE.

Austinville, Pa.
March 20, 1888.

Statistics of Consumption.

EDITOR MED. AND SURG. REPORTER:

Sir:—In the MEDICAL AND SURGICAL REPORTER for March 24, 1888, there appears an interesting though deceptive article from the pen of Dr. Sozinskey, entitled *Sex in Consumption*, which is tacitly intended as a refutation of the deductions in my paper on *Female Dress as a Determining Factor in Pulmonary Consumption*, and published in the *Medical News*, January 7, of this year. In this paper I maintain that the female is less liable to pulmonary consumption than the male, because she possesses a greater apical expansion; and had I not taken for granted in its preparation—though it appears without sufficient justification—that the absolute worthlessness of the United States census reports for securing reliable mortality statistics is universally known and admitted, this brief reply would indeed be entirely unnecessary. Any one who has had the least intelligent experience in gathering vital statistics knows full well that no data exist in this country which are worth computing except those coming from the larger cities, and perhaps from one or two of the smaller States. Outside of these sources no pretensions are even made to collect reliable mortality statistics save by the census-taker, who comes around and guesses at them every decennium. In proof of this assertion, and for the benefit of the few who still persist in hugging the delusive phantom that the census statistics are immaculate, I beg to quote the language of Prof. Francis A. Walker, Superintendent of the Ninth Census, and whose authority on this point is unquestionable. He says: "The failure of the census to reach the object proposed is perhaps nowhere so conspicuous as in the returns of the deaths occurring during the census year. The reasons for this comparative failure are not obscure or remote. Statistics of mortality can only be satisfactorily obtained as the result of a system of registration maintained without interruption and rigidly enforced by penalties. In the census of the United States, on the contrary, it is sought by an occasional enumeration to recover information of all the deaths which have occurred during the twelve months preceding. It is not wholly a matter of blame to the agents of the census that such an effort results in the return of but 60, 65 or 70 per cent. of the deaths which we know must have occurred during the period covered by the inquiry.—(The Relations of Race and Nationality to Mortality in the United States. Reports of the American Public Health Association, volume I., page 18).

It would be simple madness to anticipate anything satisfactory from such sources, and therefore I addressed myself to an examination of the health reports of all the American and foreign cities to which I could gain access, knowing that they have *a system of registration maintained by rigidly enforced penalties*, such as is described by Professor Walker, and under these circumstances I I think it requires but little "acuteness and strength of wit" to decide whether Dr. Sozinskey's figures or my own are spurious or real.

The conclusions presented in my paper I consider irrefutable so far as I know at present, and I furthermore feel quite certain that, in order to assail them successfully, a stronger armament is needed than a few quotations from the United States census report.

Yours truly,

THOMAS J. MAYS, M. D.

Philadelphia, March 26, 1888.

—Dr. O. Barbacci reports to the *Centralblatt f. d. med. Wissensch.*, the result of his estimation of the hæmoglobin with Fleischl's hæmometer in twenty-eight cases of decided chlorosis. He finds the average percentage of hæmoglobin about 44 per cent. of the normal, varying between 39 and 50 per cent. After the employment of iron for from two to four weeks an increase of the quantity of hæmoglobin to the extent of 10 to 30 per cent. occurred regularly, along with the improvement in the general health. This condition then usually continues stationary for a long time, but even in slowly progressing improvement the normal quantity of hæmoglobin is never attained.

Notes and Comments.

Malarial Congestion.

In a paper read before the Tri-State Medical Association of Mississippi, Arkansas and Tennessee, Dr. J. A. Lipscomb, of Memphis, stated that 10 per cent. of the deaths in Memphis during the months of July, August and September were caused by malarial congestion. He believes that the difference between the ordinary and the congestive, or pernicious paroxysm, is only one of degree. Cases classed as congestive may be arranged, for practical purposes, under one of the five following groups: the comatose, the spasmodic, the pulmonary, the choleraic and the algid. In the first group the poison seizes upon the brain; in the second upon the cord and medulla; in the third upon the respiratory organs; in the fourth upon the digestive organs, and in the fifth upon no special more than another, unless it be the skin. The leading indications are to bring about reaction, and then to bring the system as speedily as possible under the influence of an antiperiodic. He freely concurs in the following opinion expressed by Dr. Davidson:

"No time is to be lost in relieving the patient from the lesion of innervation and bringing about reaction. Delay in experimenting with sinapisms, plasters and stimulants is time thrown away, and will disappoint the expectations of the physician."

Dr. Lipscomb then declares: "While the depressed condition of the heart's action continues, with the serum of the blood exuding through the paralyzed capillaries of the whole mucous surface of the bowels, and the copious transudation through the skin exhausting the patient and deepening the collapse, calorification is difficult to restore. All means therefore for arousing the energy of the nervous system, and thus restoring the lost tone to the tissues, must be resorted to. What then are the means best adapted to these ends? In my humble opinion, the shock produced by the cold douche, conjoined with the hypodermic injection of morphia and atropia, or of strychnia, or of atropia and digitaline, as the indications may require."

As to the best way of applying the cold water, he has adopted the plan of pouring it from the pitcher, held as high above the patient as is convenient and allowing it to fall directly upon the back of the head and neck and down the spine. After having used several gallons of water in this way, he has the patient wiped dry with towels and wrapped in dry blankets, and given a hypodermic injection of atropia, or of atropia and morphia, or of strychnia, as may seem to be indicated. If reaction does not take place in half an hour, he repeats the douche, and wraps the patient in the blankets as before. If there is great restlessness with vomiting, morphia and atropia subserve the best purpose; if great nervous depression with sighing respiration, strychnia increases the muscular tonicity and stengthens the action of the heart, as does also digitaline.

If by these means, he says, you have succeeded in establishing reaction, lose no time in meeting the second indication, namely, that of bringing the system under the influence of quinine. He cautions the physician, however, against letting anxiety to meet the second indication get the better of his judgment, and so commence the quinine too soon. Before reaction is established and the nervous centers liberated from the depressing effect of the poison, quinine will add to the depression and sink the patient into a condition of collapse from which it will be difficult to relieve him, even if it can be done at all. He is satisfied that he has seen this happen more than once in his own practice, as well as in that of others. Having thus succeeded in establishing reaction, he advises to proceed at once to meet the second indication by the administration of quinine. The preparation of the remedy and the avenue by which it is to be administered, so as to most speedily bring the system under its antiperiodic effect, he regards as matters of grave importance. It does no good to give it by the mouth—for if it is not rejected it will not be absorbed; and the same objection may be urged to giving it by the rectum. The hypodermic method he regards as the only one to be thought of, and the bisulphate, being the most soluble, as the best preparation. One drachm of of this salt dissolved in an ounce of hot water and filtered makes a very nice solution and is less often followed by abscesses than a solution of the sulphate. One drachm of this solution representing seven and one-half grains may be injected under the skin every hour or two as the exigencies of the case may require. Since adopting this plan of treatment he has had better success than with the old one, and thinks he has saved some valuable lives.—*Memphis Med. Monthly*, March, 1888.

Salts of Nickel.

The use of nickel and nickelled utensils tends to spread more and more. M. Van Homel Ross, having recognized by various

physiological experiments, the innocuity of this metal protests against a decision of the Superior Council of Hygiene in Austria, tending to prohibit the sale of nickel cooking utensils. Dr. Blayae read the work of this learned chemist at a recent meeting of the Academy of Medicine of Paris. The opinions of chemists differ. Orfila decides neither one way nor the other; Hussel, declares that nickel is more dangerous than iron; Simpson, compares it to zinc or tin, with regard to its poisonous properties; Anderson considers it as dangerous as and similar to picrotoxine; Dragendorf declares that it is a very dangerous substance, and says that a dose of a single milligramme of acetate liquifies the globules of the blood, and destroys them. Professor Riche has made several experiments on guinea-pigs administering acetate in large doses. One died immediately of pneumonia as confirmed at the autopsy by Dr. Laborde, the other is quite well. A dog felt no ill effects after having received 25 grammes of the same salt at the rate of 50 centigrammes per day; on another dog, the dose of 50 centigrammes had no effect; it was then increased to 75, to a gramme and 2 grammes. At this last dose the animal did not die but was taken with vomiting, a chronic diarrhœa, and a sort of ataxy of the hind quarters. The symptoms disappeared rapidly when the dose of the salt was decreased to ½ gramme and the animal, which had become thin, soon fattened up again. The animal was killed and the autopsy proved there was no trace of injury. It is impossible to decide from the dog to man, but what has been shown in the course of this last experiment goes to prove that the extremely small quantity of nickel salts entering into substances cooked in vessels of this material has no hurtful effect. Nickel employed in cooking is not more dangerous than iron, which it approaches in its chemical composition.

Art in the Home from a Medical Standpoint.

Dr. I. N. Love says: "I would sooner hang in my home a ten cent chromo of a cheerful and pleasant subject, than the grandest creation of a Gabriel Max, if it present the horrible side of life as does his "Infanticide." Hanging scenes and revolting representations of morgues, may be very artistic in that they are true to nature; and even though it may be true, as has been stated (though I doubt it), that art has nothing to do with morality or immorality, I believe their proper place along with the nude in art to be art galleries and museums. And I consider anatomical and pathological pictures with skulls and skeletons as part of the belongings of a medical college, or of the inner hidden closets of the doctor's office. They are of the shop, shoppy, and in exceeding bad taste when exposed to the view of patients.

It may be true that the nude in art has rendered holy the beauty of woman and the strength of man; but I question the propriety of placing before the eyes of the undeveloped, uncultivated, or non-professional, much in the way of nude in art, just as I would hesitate to open a male and female surgical clinic to the gaze of children or a lay public."—*Weekly Med. Review*, March 17, 1888.

Influence of Obesity in Young Women upon the Menstrual and Reproductive Function.

In a paper read before the Medical Society of the State of New York, February 7, 1888, Dr. Andrew F. Currier, concluded from the testimony presented, that obesity occurring in young women caused disordered menstruation, and usually sterility, whether the patient had previously borne children or not. If utero-gestation were completed in such patients the child was likely to manifest deficient vitality. The quantity of the flow was almost always less than normal, of abnormal quality, the duration a few hours or a day. Pain was an almost constant symptom. It was in the sacral region in nearly all cases. Vicarious menstruation was common. Constipation was usually present. There was often an hereditary predisposition to early obesity. It might be brought on by luxurious habits, sluggish disposition, passive sexual indulgence, free use of starchy and saccharine foods. Suggestions as to treatment were based on the etiology.—*N. Y. Med. Journal*, Feb. 11, 1888.

Mouth-wash.

The *Chemist and Druggist*, March 17, 1888, says a teaspoonful of a lotion prepared according to the following formula, in a wineglassful of warm water, used every morning as a mouth-wash, is good for restoring firmness to the gums when the teeth are loose:

Tannin	1½ drachms
Iodide of potassium	12 grains
Tincture of iodine	1 drachm
Tincture of myrrh	1 drachm
Rose-water, to	6 oz.

Dissolve the tannin and potassium iodide in the rose-water. To this add the tinctures, and strain.

Compulsory Vaccination.

The following quotation from *The Sanitarian* would seem to indicate that a compulsory vaccination law has its advantages: "The success of the anti-vaccinationists is aptly shown by the results in Zurich, Switzerland, where for a number of years, until 1883, a compulsory vaccination law obtained, and small-pox was wholly prevented (not a single case occurred in 1882). This result was seized upon in the following year by the anti-vaccinationists, and used against the necessity for any such law, and it seems they had sufficient influence to cause its repeal. The death returns for that year (1883) showed that for every thousand deaths two were caused by small-pox; in 1884, there were three; in 1885, seventeen; and in the first quarter of 1886, eighty-five."

Wart-Charming Extraordinary.

A well-known and old-established firm of chemists in Birmingham, England, is doing a lucrative trade in charming away warts. The *modus operandi* is somewhat novel. The principal partner in the business gravely examines the warts, counts them, and instructs the patient to depart and return in a week's time. The order is obeyed, and when the individual makes his appearance on the second occasion, the chemist places on each wart a piece of bacon which he has prepared in the interim, indulges in a solemn incantation, tells the patient he must not thank him, and quickly walks away. The warts are said to wither away in the course of a few days afterwards. —*Chemist and Druggist*, Feb. 4, 1888.

The Philadelphia Polyclinic.

The remaining evening lectures in the Polyclinic course will be given on the following dates at the Polyclinic building, Broad and Lombard streets.

April 10.—Prof. Arthur Van Harlingen: The Management of Eczema in Old People.

April 20.—Prof. J. Henry C. Simes: The Treatment of the Primary Lesions in Syphilis.

April 24.—Prof. Edward Jackson: The Character and Significance of the Retinal Lesions Associated with Bright's Disease.

May 1.—Prof. Alexander W. MacCoy: Observations on the Pharyngeal Tonsil.

May 11.—Prof. H. Augustus Wilson: Treatment of lateral Spinal Curvature.

May 22.—Prof. Solomon S. Cohen: Respiratory Therapeutics.

Medical Association of the State of Alabama.

The Medical Association of the State of Alabama will hold its annual session at Montgomery, Alabama, beginning *Tuesday, April 10*, in the U. S. Court Room (P. O. Building), where the secretary and treasurer will be in attendance every morning. The first day's meeting will be largely taken up with business matters, but will include an Address of Welcome by Dr. W. G. Gibb; the Annual Message by Dr. E. H. Sholl; and the Annual Oration at 8 P.M., by Dr. B. J. Bodwin.

Wednesday, April 11.—Morning Session.—The following papers will be read:

The Value of Exploratory Incisions—William Locke Chew, M. D., Birmingham; The Radical Cure of Hernia—Luther Leonidas Hill, M. D., Montgomery; The Practical Investigation as to the Therapeutic Value of Salicylate of Hydrargyrum—Henry Tutwiler Inge, M. D., Mobile; Studies in Eczema—Arnold Jolly, M. D., Linden; Electricity in Uterine Diseases—Mortimer Harvey Jordan, M. D., Birmingham; Physiological and Pathological Heredity—James Thos. Searcy, M. D., Tuscaloosa; Diarrhœal Diseases of Children in Western and Middle Alabama—William Henry Sledge, M. D., Livingston; The Medical Topography of Walker County and its Prevailing Diseases—Alexander McAdams Stovall, M. D., Jasper; Color Blindness and Defective Vision in Relation to the Traveling Public and the Railroads—Robert Dickens Webb, M. D., Birmingham; Studies in Rectal Surgery—Benjamin Leon Wyman, M. D., Birmingham.

Evening Session.—Discussion of the best methods of administering the health laws, and the law to regulate the practice of medicine.

Thursday, April 12.—The Omnibus Discussion—Milton Columbus Baldridge, M.D., of Huntsville, leader. Topics: 1st. Typho-Malarial Fever. 2d. Hereditary Diseases. 3d. Influenza. 4th. Pain as a Symptom of Disease. 5th. The Knife in Uterine Surgery; its uses and abuses. 6th. The Medical Treatment of Old Age. 7th. Rheumatism and Gout.

Certificates are placed in the hands of ticket agents, who will furnish them to delegates and others upon application at the time tickets for the going journey are purchased, but *no refund of fare will be made on any account whatever because of failure of the parties to obtain certificates.*

NEWS.

—Cholera is still prevalent in Chili, and fears are entertained lest it may also pass the boundary into Peru.

—It is reported that Professor Fritsch, of Breslau, is to be offered the chair of midwifery at Würzburg, made vacant by the death of Scanzoni.

—The St. Louis Medical College held its annual commencement, March 8, and graduated sixteen men as physicians, and one hundred and thirteen as dentists.

—The Twentieth Annual Session of the Texas State Medical Association will be held in the city of Galveston, beginning Tuesday, April 24.

—The oldest man in Germany is called Wapniarek, and lives at Hutta, near Gresen, in the province of Posen. He was born in 1764, and is consequently now in his 124th year.

—Deaths from small-pox and yellow-fever still continue to occur at Havana, Cuba. For the week ending March 17, there were twenty-one deaths from the former disease, and three from the latter.

—An Act has passed the Iowa Assembly which requires druggists to label every package of poison they sell with two antidotes to the drug, as well as the word "poison," which is now placed on every such package.

—Dr. D. W. Cullimore states in a letter to the *Medical Press and Circular*, March 14, 1888, that he has obtained very good results in the diarrhœa of locomotor ataxia from the use of cocaine by suppository.

—French pharmacists are anxious to make and dispense antipyrine without bringing themselves into conflict with the German patents, which control its manufacture under that name. It has been suggested to make and dispense it under its proper chemical name (*dimethyloxyquinizine*), which would be awkward, or as *analgesine*.

—The *Popular Science Monthly*, April, 1888, says that Mendeljeff has, by a study of specific gravities of mixtures of alcohol and water, arrived at the conclusion that there are three definite hydrates, containing respectively three and twelve molecules of water to one molecule of alcohol, and three of alcohol to one of water. The first of these has been obtained in the crystalline form at the temperature attained by a mixture of solid carbon dioxide and ether; the second solidifies at—17°.

HUMOR.

A MAN IN A PRAYER-MEETING once prayed for the absent who were "prostrated on beds of sickness and sofas of wellness."

"THE DOCTOR SAID he'd put me on my feet again in two weeks." "Well, didn't he do it?" "He did, indeed; I had to sell my horse and buggy to foot the bill."

DOCTOR—WELL MY DEAR SIR, what seems to be the seat of your disease? Patient—It doesn't seem to have any seat, doctor. It's just jumping up and down all the while.

YOUNG MAN (AIRILY)—Excuse me, but haven't I seen you face before? Colonel Scrap (who suffers from dyspepsia)—Quite likely; I've never worn it behind.—*Life*.

OBITUARY.

THOMAS B. CURLING, F.R.C.S.

Mr. T. B. Curling, who was for many years surgeon to the London Hospital, died at Cannes, March 4. In a paper presented at his instance to the Royal Medical and Chirurgical Society, in 1846, Mr. Curling spoke of the possibility of seeing the fundus of the eye, and of the usefulness of such investigation as an aid to diagnosis. The paper thus anticipated the ophthalmoscope.

WILLIAM B. GOLDSMITH, M.D.

Dr. William B. Goldsmith, Superintendent of the Rhode Island Butler Asylum for the Insane, died at Providence, March 21, in the thirty-fourth year of his age. He succeeded the late Dr. Sawyer as Superintendent of Butler Asylum two years ago. He was graduated at Amherst College, and was educated for special practice in insanity. He passed two years in hospitals in London, Edinburgh, and Germany, and began professional practice at the Bloomingdale Asylum, New York, under Dr. Nichols. When twenty-eight years old he was called to the Superintendency of the hospital in Danvers, Mass., and stayed there until invited to go to Providence.

Official list of changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from March 25, 1888, to March 31, 1888:

Major J. P. Kimball, Surgeon, granted leave of absence for two months, to take effect about April 10, 1888. S. O. 68, A. G. O., March 23, 1888.

First Lieutenant W. D. Crosby, Assistant Surgeon, granted leave of absence for two weeks. S. O. 29, Dept. Ariz., March 16, 1888.

Captain Thomas F. Azpell, Assistant Surgeon (retired). Died March 12, 1888, at Fort Lee, N. J.

There have been no changes in the Medical Corps of the Navy, for the week ending March 31, 1888.

WHOLE No. 1624.] APRIL 14, 1888. [VOL. LVIII., No. 15.

Clinical Lecture.

LYMPHADENOMA OF THE NECK.[1]

BY PROFESSOR TERRILLON,

SURGEON TO THE SALPÊTRIÈRE, PARIS, FRANCE.

Gentlemen:—I am going to speak to you to-day of a relatively infrequent affection, of which we have a typical case in a patient 25 years of age, lying in No. 21, Ward Sainte Vierge. Last May, about six months ago, this young man first noticed a little lump under the left sterno-mastoid muscle. This swelling at first increased very slowly, but in July it became the seat, at two separate intervals, of a rapid growth, which has resulted in the voluminous mass which you see to-day.

The tumefaction which now presents itself on the left side of the neck is at least as large as the two fists, and extends from the lobule of the ear to the clavicle, and from the median line in front to two fingers' breadths behind the sterno-mastoid. The skin, which is a little red, does not take part in the swelling; the derm is free, but the subcutaneous tissue has lost its natural suppleness, and does not slide easily over the deep parts. On palpation, you find that the tumor has a lumpy feel, that there are irregular fissures, and that the whole mass is hard. If you endeavor to move the tumor, you experience a certain difficulty; it does not appear to be adherent to the subjacent bony parts, but there is a partial attachment; it extends quite deeply, and displaces the larynx, by at least two fingers' breadth, to the right of the median line. Despite all this, during the movements of deglutition the larynx and trachea rise and fall without stirring the tumor, which proves that the basis of the latter is not the thyroid body. The vessels of the region and the œsophagus seem to escape compression; there is neither œdema nor dysphagia.

In short, the tumor inconveniences the patient, but does not cause him to suffer; he feels no pain either in the shoulder, the ear, or the back of the neck. From all this we conclude that the nerves are pressed backward, but not incorporated in the morbid growth.

What has become of the sterno-mastoid? You see it distinctly only in its inferior position; you have reason to suspect that it is to be found in front of and outside of the tumor over which it is stretched; the latter extends beyond its anterior and posterior border. In the supra-clavicular hollow on both sides, and in the axillæ, you find a few glands as large as hazel-nuts. The patient has not perceptibly lost flesh or strength, and the blood when examined under the microscope does not present an excess of white globules.

After what we have just seen, the diagnosis would not seem to be a matter of great difficulty; it is a glandular affection. But what is its nature? This is the main question. You know that in the neck we may observe three sorts of swellings of the glands: 1. Acute or chronic inflammatory swelling; 2. Secondary adenopathies, consecutive to lesions more or less distant; 3. Non-inflammatory, spontaneous adenopathies.

We may at once eliminate the first variety; our patient has no trace of inflammatory affection. We can also rule out the second group; there is no lesion in the vicinity which can explain this glandular intumescence. We have inspected with care the interior of the mouth, the tonsils, the phar-

[1] Translated, with the author's permission, by E. P. Hurd, M.D.

ynx, and our examination has been negative. Moreover, you have under observation in our wards three patients who present typical cases of secondary degeneration of the glands of the neck, and you see at once that the aspect is very different from that of the patient under consideration. There remains, then, the third variety, spontaneous adenopathy. Here, if you will recall to mind what you have been before taught, you will find that this glandular affection may be arranged under four heads: 1. Tuberculous glands. 2. Simple hypertrophy of the glands. 3. Lymphoma, or lymphadenoma. 4. Lympho-sarcoma, or cancer of the glands. Let us pass in review each of these varieties, and see to which one of them the particular case now before us best corresponds.

1. When a gland is invaded by tubercle granules it increases in size, and becomes caseous, softens, inflames and suppurates, and this is what happens especially in young people. Our patient has passed the age at which we ordinarily observe this kind of affection. Moreover, his swelling is voluminous, hard, and there is no point of softening. Lastly, his general condition rules out the idea of tuberculosis, even existing as a local trouble.

2. When a gland undergoes simple hypertrophy, it doubles, triples in volume, but does not change its appearance: the glands remain independent, they do not become agglutinated; between them, in a word, there is no peri-adenitis. Lastly, if this hypertrophy becomes general, we have the *adenia* of Trousseau, with or without leucocythæmia. Now, our patient has a bunch of glands which are soldered together, but there is neither generalization nor is there any numerical alteration in the globules of the blood.

3. It remains now to examine the two last groups of our classification, and you know that it is not a very long time that we have known these lesions. In cases of lymphomata or of lymphadenomata, the glands are augmented in volume, and this hypertrophy is constituted by a modification of their structure, which may take on two forms: (*a*) The soft form, in which the cellular element predominates, and undergoes hyperplasia; the glands are then soft and almost fluctuating; (*b*) the hard form, in which the connective tissue is thickened and undergoes hyperplasia, transforming the glands into firm tumors of fibrous consistency.

Whatever may be the histological modification, it is necessary to bear in mind that this affection which takes on at the onset the characteristics of a benign tumor, may afterwards behave like the most malignant growths. The special clinical character of this kind of tumor is to begin in a single gland, and to grow by the adjunction of neighboring glands, which become agglomerated with the first one, and so on. Thus constituted, this glandular tumefaction ends by acquiring a large volume, but it presents a special characteristic, it presses back the neighboring organs and the skin without invading them, without incorporating them into itself, a property which belongs to malignant tumors. Lymphadenoma possesses already a malignant character when there exist concurrently secondary tumors, which are easy to detect when they are cutaneous (nodules described by Prof. Trélat), difficult or impossible to diagnosticate when they are seated in the liver, the lungs or the viscera. It is probably in cases of this kind that surgeons have witnessed speedy relapses and a rapid spread of the disease after the ablation of the primitive growth. Note in passing, that the cervical region, which is affected in the case of our patient, is a place of election for the localization of these glandular lymphomata.

4. Lastly, we have the lympho-sarcoma, which is only sarcoma or carcinoma of the glands. In these cases the envelope of the gland is quickly invaded and traversed, and the peripheral tissues are incorporated in the morbid mass. Lympho-sarcoma evolves rapidly; the skin is affected and ulcerated in less than ten or twelve months. Its principal character, then, is to be spread rapidly, and as it invades the neighboring tissues, it early provokes pain, which is often very intense and persistent. It will not do, however, for you to deceive yourself by supposing that pathological anatomy knows any absolute difference between lymphadenoma and lympho-sarcoma, for I have many times intimated to you that these two affections may at a given moment of their evolution present a common clinical character, namely, malignity.

After this summary survey of the subject, we may, I think, conclude that our patient is affected with lymphadenoma of the hard variety before mentioned. The progress of the tumor has been relatively slow. The glands are agglomerated, but in the midst of the common mass you detect them here and there by the little lumps which you so plainly feel; those of the neighborhood, still isolated, show us how the affection commenced; the skin is not invaded, nor are the deep organs of the region, which are only

pressed aside. Lastly, the general condition of the patient is good. Have we any means of inferring what will be the course of the disease?

Have we to do with one of those cases which become fatal by extension of the disease, even to the distant parts? Have we, on the other hand, reason to hope that this is one of those curable cases of which instances have been cited? It is unfortunately impossible in the present state of science to give a definite answer to this question; it will be necessary to wait at least until we shall have made trial of the treatment which seems appropriate to the case. It is true that the general health of our young patient is very good; there is nothing like a general extension of the disease; we have found none of those cutaneous nodules just mentioned, nor any indication of a visceral neoplasm; but we have no guaranty that there will not be an outbreak of the malady, similar to that which he suffered in July. Our prognosis must therefore be reserved.

Treatment.—As you may have inferred already, we have to choose between medicine and surgery; either we must be content to give certain internal remedies, or we must endeavor to effect total extirpation of the morbid growth.

The extirpation of diseased glands in the neck, recommended and condemned in turn by authorities, is evidently a difficult operation; it has been regarded as very questionable in cases of lymphadenoma, although, by reason of the fact that the neighboring organs are not adherent to the glands, the latter may be removed in their entirety. I could then, with safety, attempt the ablation of this glandular tumor—and there is nothing about the operation to deter me; in view, however, of the results heretofore obtained from surgical interference in cases of this kind, I think that I had better not interfere. Almost all patients who have been operated upon in like conditions have died in the course of a few weeks from generalization of the disease. I might refer you for your enlightenment to the discussion which took place in reference to this very subject at the Society of Surgery in 1877, when Professor Trélat presented his report. We shall, then, have to fall back upon the medical treatment. I shall not take up your time by enumerating all the remedial means which have been at different times proposed and abandoned, but shall speak of only two medicaments which seem to have given good results. I refer to phosphorus and arsenic. Professor Verneuil recommends the employment of phosphorus under the form of phosphorated oil:

Oil of sweet almonds.....30 parts.
Phosphorus..... 1 part.

M. Dose—Five to ten drops. Good effects are claimed from this preparation. [It has a disagreeable lucifer match taste, which causes patients soon to object to it, in which event the phosphorus can be given in pills.]

Arsensic has seemed to give better results. This medicament has been already given in cancer. Billroth, Winiwarter and Tholer have tried it thoroughly in lymphadenoma, and if it does not always cure, improvement always seems to attend its use.

The arsenic may be administered in two ways. You may either introduce it hypodermically, in which event a few drops of Fowler's solution should be injected deeply into the interstices of the swelling, or the same preparation may be given by the mouth. In the case of our patient, the swelling is too voluminous to warrant us in attempting the hypodermic method; the injections would have to be too often repeated before all the glands would be affected thereby, and besides, the administration by the mouth generally succeeds very well. We shall, then, adopt the internal treatment, which has given marvellous results; in this very hospital our predecessor, Berger, has had what seemed to be several remarkable cases from this method of treatment.

The mode of administration is important. You must begin with the minimum dose and rapidly mount up to large doses, without, at the same time, provoking any inflammatory disturbance capable of causing the glands to suppurate. Give Fowler's solution pure, or in conjunction with strychnia or nux vomica. Begin with ten drops, and in the course of a week increase to eighteen or twenty, giving the medicine before meals, and every fortnight give your patients a rest. In this way you will surely succeed in causing resolution and disappearance of these formidable swellings, whose ablation has almost always been followed by untoward results.

NOTE—The patient, who was the subject of this clinical lecture, was put on Fowler's solution Oct. 28, and the medicine was continued till Dec. 15. At this date, the tumefaction was so much diminished that it was scarcely perceptible to the sight; the glands were now separate from each other, and the patient was so well that he left the hospital. Two months afterwards he returned with the swelling as large as ever. The arsenical treatment was resumed, there was a new amelioration, and the patient again quit the hospital. We saw no more of him, but learned that he died in October of the following year; whether from the same or some other disease, we did not ascertain.—(Jan., 1888).

THE COMMON EYE AFFECTIONS OF ACQUIRED SYPHILIS.

BY EDWARD JACKSON, A. M., M. D.,
PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC.

Three of the patients in attendance to-day very well illustrate the more common and more important of the lesions of the eye, that occur in the course of acquired syphilis. Occasionally the initial lesion does occur on the eye or eye-lid, but cases of such occurrence are rare. I have never seen one. And in general the first evidence of the disease presented by the eye is an iritis, appearing as one of the secondary symptoms, in from six weeks to two years after the initial lesion. The iritis generally comes on with the eruption, or as the eruption reaches its height. And the eruption may involve the skin of the lids, or the conjunctiva, just as it may involve any other free epithelial surface of the body. Here is our case of

Iritis.

J. M., aged 35, had a chancre about four months ago. For six weeks he has had this well-marked and characteristic eruption; and during that time he has been decidedly out of health, and has been under medical treatment, the exact nature of which we do not know. About three weeks ago his left eye got "sore;" that is, it became red, over-sensitive to light, there was excessive secretion of tears, and pain in the eye and in the neighboring brow and cheek, often very severe, especially at night. This condition continued growing, on the whole, rather worse; until he presented himself at the clinic, about ten days ago. At that time, you will remember, he complained of the symptoms just enumerated, and on inspecting the eye we found by oblique illumination that there was a zone of hyperemia surrounding the cornea; that the cornea presented opacities, but that its surface was smooth; that the iris was of a color slightly different from that of the healthy right eye, and that the pupil was slightly dilated, the latter condition being due to the use of an eye-water, which contained some mydriatic, though not enough of it to dilate the pupil properly. After the instillation of a solution of

Atropia sulphate.....1 grain
Water.....1 fluid drachm,

we found that the pupil dilated to almost the normal extent in every direction, except upward and inward, where there was a distinct projection or swelling of the iris. Opposite this projection of the iris there was a single spot of opacity on the anterior capsule of the lens where the pupillary margin of the swollen part of the iris had rested, prior to the dilatation of the pupil which had torn through this single adhesion. The corneal opacity mainly affected the lower portion of the cornea, and was situated near or upon the posterior surface of that membrane. In brief, we had here a case of iritis, mainly serous, but which had at one point become plastic; with well-marked punctate keratitis, and a history of recent syphilis.

There is a common impression that syphilitic iritis is always plastic, but it is often in the beginning serous, only there is no tendency to spontaneous recovery, and if not subjected to the proper line of treatment it runs on, almost invariably into a plastic inflammation, and often beyond this, to the formation of gummata in the iris. It is, on every account, important that the nature of the affection should be recognized, and the proper treatment inaugurated in the earliest stage, when a complete cure may be effected.

This man was put upon the one-sixth of a grain of calomel four times a day. When this had produced rather free purging, we tried the green or prot-iodide of mercury, but this in one-fourth grain doses, seeming to cause even more gastro-intestinal irritation, we returned to the use of the mild chloride, adding to each dose double its amount of powdered opium, which prevented any further diarrhea. This, the specific part of the treatment, has been continued up to the present time. We also gave at first quinia sulphate two grains three times a day, but this was discontinued as soon as improvement was well under way. Locally, he has used a solution of atropia sulphate, one-half the strength of that given above, three times daily; preceding each instillation, of one or two drops, by bathing the closed lids and the neighboring parts with water as hot as he can bear it. This local treatment will be continued; but as he is now markedly anemic we shall have him take internally, in place of the calomel,

Hydrarg. chlorid. corrosiv.....gr. ij
Tr. ferri chloridi.....f℥ iv
Fifteen drops, freely diluted with water, twenty minutes before each meal.

The eye is already free from hyperemia, and the dots of opacity at the posterior surface of the cornea are rapidly disappearing. Probably in two or three weeks the opacities will all be gone, and the only permanent mark of the disease of the eye will be the single speck of iris pigment left adherent to

the anterior capsule of the lens. Had the iritis become fairly plastic, with the formation of strong adhesions, recovery must have been much slower and less complete. But with the recovery of his eye he must not discontinue the specific treatment. Many months must elapse before he can be free from danger of another attack, or a similar invasion of the other eye. Syphilitic iritis is prone to affect both eyes, though often not at the same time, and by proper treatment the involvement of the second eye may be avoided.

Paralysis of the extra-ocular Muscles.

P. S., aged 55, came to the dispensary over two months ago, saying that for two weeks he had been suffering severe pain of an aching character in the right brow and temple, that he saw double, that he could not open the right eye, and that these symptoms, while appearing in the first place rather suddenly, continued to grow worse. On examination it was found that there was loss of power to raise the upper lid of the right eye, and inability to turn the eye up or down or toward the nose. If he looked at an object directly in front of him, or to the right, and about on a level with his eyes or a little below them, he saw it single. But on attempting to look in any other direction, the left eye moved properly, but the right, failing to make the attempted movements, paralytic squint occurred, causing the diplopia of which he complained. He had paralysis of the muscles supplied by the third cranial or oculo-motor nerve with pain referred to the ophthalmic division of the fifth nerve. Now, by far the most common cause of such a group of symptoms is a syphilitic new growth near the point where these nerves enter the orbit. We asked the patient about syphilis, but he denied ever having had it. We then inquired for rheumatism and other possible causes of such a lesion, but finding none fell back upon the probabilities of the case, and put the patient on the use of iodide of potassium, ordering

Potassium iodide..... 1 ounce
Water, sufficient to make... 1 fluid ounce,

each minim of this solution containing about one grain of the iodide. The advantage of such a solution is, that with it the dose can be so easily, accurately, and steadily increased. He took it well diluted with water, an hour or more after meals, at first ten drops three times a day, but increasing the dose every two or three days, until in a few days he was taking forty drops four times a day.

When the patient first applied, the paralysis of the superior, inferior, and internal recti, and of the elevator of the upper lid was almost complete, and three days later it was absolute. But, by the time he was taking one hundred and sixty grains of potassium iodide daily, improvement was quite noticeable, and although there were no symptoms of iodism, the dose was not afterwards increased. The return of muscular power was first apparent in the elevator of the upper lid; the ptosis diminished rapidly. By the time he could, by an unaided effort of this muscle, uncover the whole of the cornea, there was some return of power in the superior and inferior recti; and a little later the internal rectus was able to turn the eye somewhat toward the nose. At the end of a month of treatment the drooping of the lid was entirely gone, and the eye could be moved quite freely, vertically or toward the nose, but there was still diplopia at the margins of the field of binocular vision in all directions except to the right, or a little upward and to the right. We now began to suspect what had before had been masked by the oculo-motor lesion, a paresis of the superior oblique muscle, supplied by the fourth cranial nerve. With the complete recovery of the third nerve, the weakness of the fourth became quite obvious, the double vision being, a few days ago confined to the lower right side of the binocular field, and the position of the false image varying as it would in such a condition. But this also was improving soon after it was discovered; and now, at the end of the seventh week, there is no diplopia, and the movements of the eye seem in all respects normal.

This patient's denial of any earlier manifestations of syphilis raises the question of our ability to diagnosticate the tertiary period, or sequellæ of syphilis, from the symptoms alone; and particularly by the tolerance of very large doses of potassium iodide. Perhaps we are not, by such evidence, justified in making the positive, unqualified statement that this man has had syphilis; but for all practical purposes of prognosis and therapeutics we may, in a case like this, consider the diagnosis settled.

Central Retinitis.

D. M., aged 42, had syphilis six years ago. The right eye has been lost by some general inflammation, leaving an occluded pupil, for which an iridectomy has been done without any practical benefit. He says that about seven months ago he first noticed a cloud before the left eye, the good one, which grew

denser day by day, and was most dense just in the direction that he attempted to look. He applied at one of the public clinics in the city, and received treatment under which his sight stopped getting worse, but there was no subsequent recovery of vision. He states that the drugs then employed included mercury to salivation, and potassium iodide to the amount of one hundred and sixty grains a day. During the months that have elapsed since he discontinued treatment, he thinks there has been no further change in his power of vision. When he first came here, two weeks ago, the appearances presented by this eye were precisely what they are now. Externally, we only notice that the pupil which presents one posterior synechia, seems a trifle large for a man of his age; and that when he attempts to see an object he does not look directly at it, but a little above or below it, or to one side; and in a somewhat prolonged effort to make out a letter on the test-card his eye roves all round it. With the ophthalmoscope, the retinal vessels, especially the arteries, seem rather smaller than is usual. The disk, besides being quite pale, is partially obscured by a faint gray cloud, through which the margins and the smaller vessels are seen quite indistinctly. Away from the disk the appearance of the fundus is normal, except in the region of the yellow spot. Here we see a grayish white area, irregularly oval, somewhat larger than the disk; and shading off into the normal fundus, in some directions abruptly, in others, very gradually. Some of the fine terminal branches that run in toward the fovea are buried in the mass which causes this appearance; and at no point is there any noticeable disturbance of the pigment layer. We cannot say that the choroid underlying this region is entirely normal; but so far as we can see, the morbid process is confined to the retina. And except that there was, probably, more hyperemia then, it is not likely that the appearances presented at the beginning of the attack were materially different from those we observe now.

Although there is every reason to think that this lesion was in its origin syphilitic; from his having undergone at competent hands a vigorous course of anti-syphilitic treatment, from the length of time that had elapsed since the original onset, and from the diminished vascularity of the affected parts; we concluded that the actual condition now to be dealt with was not a specific morbid process, but a process of atrophy of the nerve tissue, such as might follow any form of plastic inflammation of the optic nerve or retina. Acting on this view we ordered the use of strychnia, at first in doses of one twenty-fourth of a grain three times a day. The dose has already been increased to one-twentieth, and to-day we shall increase it to one-sixteenth of a grain. And having warned the patient to be on the lookout for any muscular soreness or twitchings, or stiffness about the neck or jaws, the first symptoms of poisoning by the drug, we shall continue from time to time to increase the dose until the occurrence of some of these symptoms warns us that the limit of tolerance has been reached. Already the patient says there is some improvement in his vision; and improvement is likely to be more marked and more rapid as the full physiological dose is approached. (Subsequently the dose was increased until it reached one-sixth of a grain three times a day, when slight evidence of the toxic action of the drug was noticed. Vision improved from $\frac{15}{200}$ to $\frac{15}{70}$, but remained entirely eccentric, the centre of the macula being still quite blind. There was, however, marked extension of the periphery of the visual field, and very considerable diminution of the central scotoma.)

Communications.

GRADUATED TENOTOMY IN THE TREATMENT OF INSUFFICIENCIES OF THE OCULAR MUSCLES. (STEVENS'S OPERATION.)[1]

BY CHARLES H. THOMAS, M.D.,
PHILADELPHIA.

The study of disorders of the ocular muscles in relation to functional nervous diseases has received a strong forward impetus during the past year, chiefly due to the published results of the labors in this direction of Dr. George T. Stevens, of New York, whose work on "Functional Nervous Diseases," recently published,[2] has challenged special attention, even where it has not met with entire approval. The subject occupies a standpoint on the line between the two important specialties of ophthalmology and neurology, it takes somewhat from both, and has already, by force of circumstances, become in a certain sense a specialty of itself. The operation and its application have, until recently remained to a remarkable degree personal in

[1] A paper read at the meeting of the Philadelphia County Medical Society, March 14, 1888.

[2] D. Appleton & Co., N. Y., 1887.

the hands of Dr. Stevens, notwithstanding that for many years he has reported it before medical societies and in the medical journals.[1]

All this, however, has been recently changed by the publication, within the last year, of his work above referred to, which has brought the method into such prominent notice, as to compel recognition. Other operators have now entered the field, among whom is Prof. A. L. Ranney, of New York City, who, as a neurological specialist, has reported[2] a series of cases of the gravest neuroses successfully treated by the Stevens's method. Beyond question a point has now been reached which shows the subject to be worthy of the most sincere investigation.

What I have to present to-night is, to a certain extent, in the nature of a preliminary report; as my work is necessarily incomplete in some particulars, owing chiefly to the considerable length of time required for observation to arrive at a just estimate of the permanency of the results obtained—especially in the gravest and, therefore, most important cases. I shall attempt to add little that is new to the presentation of the case as made by Dr. Stevens himself, and I cannot hope, in the length of time allotted for its consideration, to make a statement commensurate with its importance, but I have thought it right to rehearse briefly its principal features and to give my own experience in connection therewith, together with a sketch of a few of my own cases; because I have become convinced of the importance of the subject, and also because it has not, heretofore, been brought before this society—nor, so far as I can learn, before any other of the medical societies of Philadelphia. It is now about ten years ago that the operation was first brought to my notice by patients who had been under Dr. Stevens's care. It seemed to me incredible that results such as they claimed were produced in their cases, could have been derived from the cause assigned. Again, I questioned the practicability of performing the operation in the definitely graduated manner which was said to be practised by him. Under these circumstances, and in the absence of better information, my position was for a long time one of earnest opposition to the practice in question.

About three years ago, however, having under my care several cases of muscular asthenopia which I was unable to relieve, though I obtained the advice of several of the best known ophthalmologists, and being freshly reminded of the work of Dr. Stevens by a patient of unusual intelligence and reliability, who reported great relief obtained at his hands, I asked his assistance in the treatment of these cases. He kindly demonstrated to me, upon patients of his own, the practicability of the operation, and I became convinced of its great value. The results obtained were so satisfactory that since that time I have investigated the muscular as thoroughly as the refractive conditions in all cases coming under my care, and have as faithfully undertaken to correct them.

For the discovery of abnormality in any of the straight muscles, their physiological condition, both while at rest and in action, and in all states of the accommodation of the eye must be thoroughly understood. In order that binocular vision may result, the visual lines of both eyes must converge upon the same point, whatever may be the position and distance of the object. It is only under such circumstances that the rays of light are brought to a focus at corresponding points upon both retinæ. A slight deviation results in diplopia, constituting strabismus, a subject sufficiently well understood, and to which Stevens's researches do not directly apply. But while there may be perfect binocular vision, and not the slightest indication of strabismus, there may be, nevertheless, grave faults affecting the recti. It is these faults that Dr. Stevens has emphasized, and to these his observations have been chiefly confined.

In the normal condition of the ocular muscles the visual lines of both eyes naturally preserve an almost exactly parallel direction when looking at distant objects; and they maintain such a position of their own accord from muscular tonicity alone, without the necessity of any additional stimulus. This can be shown by prismatic tests. The artificial diplopia produced in making the test will be such that the two images will lie in that plane which is at right angles to the base of the prism.[1] If, for example, diplopia be induced by a prism placed before either eye with its base directed either outward or inward, the two images will lie in the same *horizontal* plane; and, similarly, *vertical* prisms, with base up or down, will induce

[1] See articles by Dr. George T. Stevens, on "Chorea" (*Medical Record*, 1876), on "Anomalies of the Ocular Muscles" (*Archives of Ophthalmology*, June, 1877.)

[2] "The Treatment of Functional Nervous Diseases by the Relief of Eye Strain," *New York Medical Journal*, January 7, 1888.

[1] Not that Dr Stevens was by any means the first to employ prisms for the discovery of muscular irregularities, but he appears to have used them with greater precision and by more systematic methods than have heretofore prevailed.

diplopia; but in this case the two images will be situated in the same *vertical* plane. The reason for this is because the normal visual lines of both eyes naturally lie in the same *horizontal* and *vertical* planes, even when the powerful stimulus which the need of binocular vision presents is abolished by the prism. Hence, if the eyes in the normal state be directed to a distant object, binocular vision will occur without the need of extra muscular action to bring the visual lines to properly bear upon the object. If, on the other hand, the visual lines of the two eyes do not naturally take the proper position, one of the two things will result, either there will be no effort to bring them into correspondence, and strabismus with attending diplopia occurs, or, *more frequently*, by an extra nervo-muscular effort, called into action by the demand for binocular vision, the proper position will be maintained; just as in facultative hypermetropia accommodation is necessary even when parallel rays coming from a distant object are to be brought to a focus upon the retina. From this forced, though it may be involuntary or even unconscious effort to maintain the proper direction of the visual lines, the abnormal conditions under consideration result. We have abundant clinical evidence of the enormous expenditure of nerve force under these circumstances, and of the development of marked reflex disturbances, which are manifested both in symptoms of irritation and exhaustion.

Dr. Stevens has[1] introduced a series of terms descriptive of the various abnormalities to which the recti muscles are subject. The word *exophoria* designates simply an outward tendency of the visual lines, without implying anything as to which muscle or set of muscles is at fault. The opposite condition, namely, tendency to convergence, is designated by the word *esophoria*, meaning an inward tending.

If either visual line deviates above its fellow, the fact is expressed by the term *hyperphoria*, right or left, as the case may be, always remembering that the lower image represents the higher-tending visual line. It is to be remarked that the condition of hyperphoria is far more frequently productive of serious reflex disturbances than any other fault, and mainly for the reason that a small amount of deficiency in this direction may, and usually does, involve a considerable proportion of the total coördinating power of the vertical muscles; and this because the power of sursumduction is usually limited to about three degrees, while that of abduction is about eight degrees, and that of adduction may be fifty degrees and upward.

The generic term to express any deviation whatever from *orthophoria*, the normal, is *heterophoria*.

Finally, the amount of heterophoria found in any given case is equivalent to and expressed by the degree of the prism required to correct the fault.

In practice, the tests for insufficiency are made by placing prisms before the eyes with their bases in certain definite directions. Lateral diplopia is produced by a prism with base in, vertical diplopia by a prism either up or down. If in lateral diplopia so induced, either image is above the plane of its fellow, we know that the higher image belongs to the eye whose visual line is lowest, to be expressed as hyperphoria of the opposite eye. If, in induced vertical diplopia, either image deviates from the vertical, we have lateral fault—esophoria, if the diplopia be homonymous, exophoria, if crossed.

In applying the prism test for the discovery of muscular anomalies it is not sufficient to be content with the results of a single or even several examinations, because we must always bear in mind the possibility of latency—that is to say, like latent hyperopia, the true fault may be concealed or masked. Indeed, as in latent hypermetropia we sometimes have apparent myopia through spasm of the muscle of accommodation, so in actual esophoria an apparent exophoria may be manifest, the result of spasm of the externi, and this is equally true of the other muscles. It is only by a careful consideration of the circumstances, such as the degrees of abductive and adductive power; and, finally, by the use of temporary correcting prisms for whatever fault may be manifested, and following it up —but not leading it—as it develops, by a new correcting prism until the fault becomes stationary, that we are justified in proceeding to operation. In one obstinate case of exophoria I have several times obtained relaxation of spasm of the interni by a moderate dose of morphia administered hypodermically. But, though the after results proved the observation under morphia to be expressive of the true condition in this case, there are obvious objections to the use of the drug as a matter of ordinary practice. The discovery of an efficient and safe agent for the relaxation of spasm of the recti muscles is greatly to be desired. It sometimes happens that muscular anomalies of considerable de

[1] "A System of Terms relating to the Conditions of the Ocular Muscles known as 'Insufficiencies,'" by George T. Stevens, M.D., Ph.D. (*New York Medical Journal*, December 4, 1886).

gree are discovered in connection with refractive faults. By correcting the refractive error first not infrequently the muscular difficulty soon disappears, showing the muscular to have been dependent upon the refractive state. The correction of refractive errors, especially those of a hypermetropic character should always be made before applying the prismatic tests. Defects of refraction and accommodation are well known as the source of serious reflexes, especially headaches or severe migraine, nausea and dizziness; but it is not so well known that defects of muscular adjustment through faults of the guiding muscles of the eye produce all these and many more serious results besides.

From Dr. Stevens I quote:[1] "Respecting the importance to be attributed to ocular, refractive, and muscular anomalies, I fear that my views will for some time to come continue to be regarded as something more than radical; but I am ready to reaffirm the proposition made years ago, that, among the various elements constituting the neuropathic tendency, these anomalies must be regarded as occupying a preëminent position.

"Summing up the experience in this field of work, it is shown that, not in occasional and rare instances only, but in a large proportion of cases of the most redoubtable neuroses, unusual and most salutary results may be anticipated from attention directed to visual troubles."

Among the neuroses shown in many cases to be dependent upon such troubles, are to be mentioned neuralgia, spinal irritation and neurasthenia, chorea, epilepsy, and mental disorders. Dr. Stevens further says: "Not only are those painful or irregular conditions usually described as neuroses in great proportion responsive to the relief from ocular tensions, but a great variety of conditions commonly regarded as local affections yield as readily, and prove that with some possible local complications they are, in fact, reflex phenomena. As an instance of this class of trouble, I may mention the fact that in more than a score of cases of extreme dysmenorrhœa—in each of which the periodical suffering has been of intense character, of regular occurrence, and of the full duration of the menstrual life of the patient—the dysmenorrhœa has failed to occur after relief to the tension of a superior or inferior rectus."

"So far as my experience goes, epilepsy very rarely results from simple conditions. The ocular anomalies in epilepsy are of the most complicated, and often of the most obscure character. A simple insufficiency may induce headache or other minor manifestations, but the ocular causes of epilepsy are usually of a character most perplexing to the surgeon, and sometimes of a character which cannot be completely remedied. Hence, great patience, and, in certain cases, much time and skill are required to accomplish that which can finally be done. If, in the meantime, the patient and his friends are constantly assured by both lay and professional advisers that his efforts must, of necessity, prove fruitless, he is apt to withdraw from treatment, even while defects which are of great importance, are known to exist, and which, by continued efforts, might be removed."

Prof. Ranney is authority for the statement that in cases of epilepsy of long duration under treatment directed to ocular difficulties, the affection has been scarcely less tractable than diseases commonly regarded as easily curable. As furnishing a suggestion as to the possible method of production of epileptic attacks from eye-strain, it is interesting to note some experiments performed several years ago by Drs. Dercum, Parker and others in the artificial induction of convulsive seizures. They found that it was possible to produce spasms in many persons by the following method:[2]

"The subject being seated, the tips of the fingers of one or both hands were so placed upon the surface of a table as to give merely a delicate sense of contact—*i. e.*, the fingers were not allowed to rest upon the table, but were maintained, by a constant muscular effort, barely in contact with it. Any other position involving a like effort of constant muscular adjustment was found to be equally efficient. Any one object in the room was now selected, and the mind fixed upon it, or some subject of thought was taken up and unswervingly followed.

"After the lapse of a variable period of time, extending from a few minutes to an hour, and depending upon individual peculiarities to be noted, * * * * the subject was frequently thrown violently to the ground in a general convulsion, preceded by tremors which rapidly became more violent.

"Seizures equalling in violence a general convulsion were by no means induced in all subjects, and were generally the result of experiments repeated many times during the same evening. In the experimentors the con-

[1] See "Ocular Irritations and Nervous Disorders," by Dr. George T. Stevens. *N. Y. Medical Journal*, April 16, 1887.

[2] See "Artificial Induction of Convulsive Seizures," by Drs. F. X. Dercum and A. J. Parker. *Journal of Mental and Nervous Diseases*, October, 1884.

vulsions became so easily induced that it was thought advisable to desist for a long period."

The *effort of constant muscular adjustment* here spoken of appears not unlike the condition found in the eyes in cases of insufficiency of the ocular muscles; and it seems not unreasonable to infer that if such strain of the muscles of the forearm would produce results of the kind reported by the authors just named, that the strain upon ill-balanced ocular muscles (which must be continuous during the whole of the time that the eyes are opened) should be productive of even more serious, and, indeed, permanent results. In the great majority of these cases there is but one satisfactory method of treatment, and that is graduated tenotomy. The operation consists in making a small opening through the conjunctiva, exactly over the insertion of the tendon, when the tendon is seized by extremely fine forceps and divided outwardly in each direction, preserving the extreme outer fibres, or, at least, the reflection of the capsule of Tenon, which serves as an auxiliary attachment. Tenotomies for strabismus and so-called partial tenotomies have, of course, long been made, but there are radical differences between these and the operation here described. The fan-shaped expansion of the tendons of the recti at their points of insertion into the sclerotic are somewhat wider than is generally supposed, while the elasticity of their edges is an influential factor in determining a favorable result in the purpose of the operation—that is, in bringing about a relaxation which shall be permanent by permitting the divided portion to retract and form a new attachment to the globe further back.

The use of prisms as a means of treatment of marked heterophoria is not to be relied on; as in many cases they are found to be insufficient and disappointing.[1] They, however, have a certain value as means of systematic exercise of the ocular muscles, particularly in the milder cases. When the correction is made by tenotomy, all that is necessary to be done in a given case should be regarded, in a sense, as one operation, though it may be in several stages and at different periods—as a watchmaker counts the regulating of the watch one operation, though he may be obliged to move the regulator a number of times; or as the correction of an astigmatism is one operation, though it may involve a number of sittings.

In one complicated case I have operated as many as seven times; the first operation nearly two years, and the last a week ago; the net result being an unquestionable gain both in head symptoms, which were at one time alarming, and in the severe asthenopia to which the patient had long been subject. Previous to the operation she had suffered from severe pain in the region of the eyes and in the back of the head, accompanied by general nervous distress of an entirely disabling character. An eminent ophthalmologist declared her to have organic disease at the base of the brain from the appearance of the eye ground. This was about three years ago. To-day this lady assured me that she felt "wonderfully better," and expressed her entire satisfaction with the treatment she had received.

It is to be re-emphasized in this connection, as an additional caution, that no operation is ever to be undertaken unless the indications for it are positively made out. From a perfectly plain case, evident to the merest tyro, to one demanding the greatest skill and patience of the most experienced, there is every gradation. Nothing would tend more to bring discredit upon the procedure than premature operations, which might result in such disturbance of the ocular muscles as seriously to cripple binocular vision without in the least alleviating the reflex condition for which the operation was undertaken.

Mrs. G. H. C., referred to me by Dr. W. H. H. Githens, aged 32, married, mother of four children. Has suffered for many years from almost constant severe headache combined with a feeling of drowsiness, the seat of the pain being the brow and vertex. Eyeballs painful, always felt better when the eyes were closed. There is frequently double vision, but no manifest strabismus. General condition markedly neurasthenic. Although there was no error of refraction except a very slight amount of hyperopia shown only under full mydriasis, the patient was unable to use her eyes at any near work, such as reading, sewing, etc., and at all times suffers from extreme intolerance of light. Ophthalmoscopic examination negative.

Muscular tests. The first examination showed an esophoria of nine degrees, which, under the use of partially correcting prisms worn for ten days, developed into settled fault of twenty degrees of esophoria and twenty-eight degrees esophoria in accommodation. Tenotomy of the left internus relieved all the

[1] Since this paper was written a physician of this city—himself an accomplished neurologist—who habitually wears spectacles for the correction of refractive errors and who also suffers from muscular faults, in a conversation with me, said with emphasis, "It is *impossible* for me to wear prisms. I have tried them thoroughly and know they would drive me crazy."

BEFORE AND AFTER OPERATION UPON THE EYES.

BEFORE OPERATION.

ONE WEEK AFTER OPERATION.

[Prepared from the photographs exhibited by Dr. Charles H. Thomas to the Philadelphia County Medical Society. See *Medical and Surgical Reporter*, April 14, 1888, page 465.]

muscular fault except one degree, which I have allowed to remain. The relief of all symptoms was immediate and complete. The headache, the pain in the eyes, the intolerance of light, the drowsiness and double vision have all vanished. She is now able (without the aid of glasses) to read and sew as well as anyone, and threading a needle, which, previous to the operation, was almost an impossibility for her, is now done with facility. The general health and spirits have improved to a remarkable extent. The photographs in her case are from untouched negatives, taken under photographic conditions as nearly identical as possible. The first photograph accurately represents her condition at the time of the operation. The strained look of the eyes, and the high condition of nervous tension are in no way exaggerated. The second photograph was taken one week after the operation, though it might, indeed, have been taken a day afterward—the immediate relief was so great. Perhaps no change in her condition is more marked than that of her tone of voice, which, from being high-pitched, nervous, almost wailing in character, has been moderated, mellowed, and vastly improved. The photograph of this case gives a clearer idea than words can do of the change which may be wrought by operation—in her case a single operation.

As additional graphic illustration of what may be accomplished, I pass around a few photogravure proofs belonging to Dr. Stevens, which he has very kindly placed at my disposal.

J. H. W., thoroughly healthy boy, without any nervous symptoms whatever, has been under my oversight since infancy. Except for a chronic tarsal ophthalmia there was nothing to call attention to the eyes. Very slight hypermetropia, for which I had prescribed glasses several years ago. On examination, three months ago there were eleven degrees of esophoria manifest, for which an operation was performed, removing seven degrees of the fault. Two weeks later four degrees additional were manifested; a week later the total manifest esophoria was nine degrees, when a second operation was performed, resulting in the removal of eight degrees of nine then existing. A recent examination shows a manifest esophoria of three degrees, being a let-out of two degrees since the last operation.

From the first operation a marked change took place in his facial expression; his eyes, which had been previously almost closed, opened widely, the tarsal ophthalmia showed prompt improvement, and he expressed himself free from a constant struggle to keep the eyes from closing, which he had not recognized as dependent upon any condition of the eyes until after it had been relieved.

I present the patient this evening for the purpose of demonstrating the amount of setback given to the tendon, which, though invisible under ordinary circumstances, may be readily seen, upon causing either eye to be rolled outward, as a vertical line in each eye about two millimetres wide in one, and a little less in the other, where the sclerotic is plainly visible through the conjunctiva.

Whether the claim made that the neuropathic predisposition is more frequently due to eye strain than to other conditions is fully justified by the facts or not, it is unnecessary at present to determine; seeing that enough is known to make it certain that eye strain from muscular fault is the cause of grave and varied reflex neuroses; and that in these cases carefully graduated tenotomy promises relief; beside there is in such cases always sufficient justification for the sake of the eyes and sight—apart from the nervous condition—for the correction of the fault.

My own experience covers many of these operations, performed for the relief of a variety of conditions, and notwithstanding serious difficulties at times encountered, I have a steadily increasing confidence in the legitimacy and value of the method.

THE OINTMENT OF THE NITRATE OF MERCURY AS AN ABORTIFACIENT OF BOILS AND FELONS.

BY ROBERT C. KENNER, A.M., M.D.,

LOUISVILLE, KY.

For the last six years I have used the ointment of the nitrate of mercury as an abortifacient of boils and felons with a degree of success that has followed upon the use of no other agent for the same purpose. I have been able to abort nearly all the cases of boils and felons, which I saw before they had begun to suppurate. The application of the ointment is not painful, and in about twelve hours the pain disappears, and there is a peculiar "drawing" sensation which continues several hours, though it is not unpleasant, and then follows a complete cessation of all pain and uncomfortable sensations.

In describing my method of using the ointment of the nitrate of mercury for this purpose, let me detail several cases: J. J., a ferryman, came to my office complaining of pain in the forefinger of the right hand. It was red and hot, and caused him pain when he used

it. Increased tenderness was made out about one spot. He had suffered from felons before, he said, and was sure that this was an incipient one. I felt assured of this, and covered the entire finger with the ointment to the thickness of an eighth of an inch. I then put a piece of thick sticking-plaster around the finger, and had the edge of one side to overflap and adhere. The end was folded and sealed by thinner plaster. I then had him to put his arm in a sling, and instructed him not to take it out, or use it in any manner. I gave him a prescription for morphine granules, telling him to use them should his finger become very painful. The dressing was to remain on twenty-four hours, at the end of which time he was to report. He returned next morning, when the red, hot and painful condition which yesterday was evidently a developing felon, was now materially changed. The finger was pale, and it caused him no pain to make pressure on it. He said the pain had ceased about ten or twelve hours after the application of the ointment, and he did not have to use the morphine. I did not think further application of the ointment necessary, and he was allowed to go about his business, and suffered no recurrence.

S. B., applied for treatment for an incipient boil. She had one a short while before, which had gone to maturation, causing her much pain and annoyance, and she wished if possible to have this one aborted. It was on the wrist; it was red, painful and hard to the touch. The skin around was red and hot, but there was no evidence that any pus had yet formed. I applied the ointment over the boil and the adjacent red surfaces to the thickness of an eighth of an inch. She was instructed to take morphine granules if necessary, and to keep her arm in a sling, and to call at the office on the following morning. By this time, the boil, which before was beginning to assume its peculiar ovoid shape, and was hot, angry and red, had become pale, greatly diminished in size, and to a great extent absorbed. It seemed to be only a question of a short time for it to be entirely resolved, and I told her she might leave off the dressing when she went home. I had her to commence taking iron and quinine, and she not only had no further trouble from this boil, but was free from further recurrence of them.

In employing the ointment for this purpose to the neck, to the buttock, and several other parts of the body, the ingenuity of the physician will be called into play. The thick plaster which is to hold the ointment against the neck, may be held in place by small strips of thin adhesive plaster. But in warm weather, or in heated rooms, the ointment may become warm and run out from beneath the edges of the plaster. Especially is this likely to be the case, if the patient insists on going about his business. Much of this trouble can be avoided, by having the patient assume the recumbent position for the time. I insist on this as a necessary condition, and find few patients, who will not agree to accept it.

When there has been any formation of pus in the boil, the abortive powers of the ointment of the nitrate of mercury must not be depended upon, but I have frequently seen cases very favorably modified by it. When the boil has attained considerable size, and that peculiar place of softness, and often after the patient has felt the "throbbing and beating" which they describe, for several days, I generally conclude there is little or no hope of aborting it. Some cases will put us in doubt, and in these it is well to try the remedy. In one case I tried the remedy, when I felt there was little chance if any; and found while I did not abort it, that I had circumscribed the growth of the boil—and the annoyance which it produced subsequently, was greatly less than it otherwise would have been. But when the boil is large or very painful and we think pus is forming, it is not best to use the ointment. Poultices applied locally and anodynes internally should be relied on till the proper time to lance it has arrived. So, also with the felon; when we feel that the time has gone by when it might have been aborted, it is not advisable to use the ointment, because no good can come of it, and the pain which is generally agonizing will not be relieved to any extent. But if the inflammatory process has been essentially mild, the ointment may be tried in hope that it may still be cut short. But in those who come to us with the history of several sleepless nights, and unmistakable symptoms that lead us to believe that to temporize is to add to the patient's trouble, there can be no good result from delaying the free use of the knife, in hope of aborting a process now entirely beyond such a possibility.

The proper field for the use of this agent then is in the treatment of boils and felons which have not gone to such a degree of maturity in the one case, that pus has formed in its center, and in the other when we are sure the inflammatory condition has not gone beyond the primary and abortive stages.

This method of the abortive treatment of boils and felons is superior to several ways of treating boils and felons with this result in

view, in that it is easy of application—it is very simple, and unattended with pain.

DISEASES AND THEIR TREATMENT IN ARMENIA.

BY WILLIAM B. DEWEES, M.A., M.D.,
SALINA, KANSAS.

Some time ago I had the pleasure of listening to a very interesting lecture on "The Habits and Customs of the Native People of Armenia," delivered in a very pleasing manner, in English, by Mr. N. A. Morjickian, a native-born Armenian, who came to America about four years ago, unable to speak a word of English, or any other language except his native tongue. His object in coming to this country was to be educated in the literary and theological institutions of the United States, and afterwards to become a missionary, under the auspices of the Lutheran Church, among his own native people. He is at present pursuing his studies at the Denver University, Colorado. After the lecture I made his acquaintance, and found him very pleasant and interesting in conversation, giving evidence of being well informed on general topics of interest in this country. I finally asked if he would have any hesitancy in answering some questions relative to the diseases and their cure by his countrymen? He assured me he would take pleasure in responding, and the following letter may be of interest to the readers of the REPORTER:

"DENVER UNIVERSITY,

"Denver, Colorado, *Feb. 7, 1888.*

"*Dr. W. B. Dewees, Salina, Kansas.*

"DEAR FRIEND:—In reply, according to my promise, to your letter of inquiry regarding the diseases and their cure by the natives of my country—Armenia—I shall endeavor to give you a brief account. I will not repeat your queries, but will give the number in the order in your letter, and the answer to each respectively.

1. "*Cause of disease.*—The superstitious people attribute disease to the wickedness of the parents of the diseased one, and also to the diseased man's or woman's negligence of religious rites; but the more intelligent class attributes disease to the disorder of the organs of the body.

2. "*Medical education.*—Our physicians are not educated people; they consist of a class of wise old women who discover and classify, and treat diseases from observations.

3. "*Medical accomplishments.*—Inasmuch as they are not trained in medical science, they have no true accomplishments in that department. They must be of good reputation as to their moral condition.

4. "*Headache.*—This is cured by bleeding the nose or drawing some blood from the temples. No internal application or administration of anything.

5. "*Colic.*—I have seen dozens of times people suffering most intensely from colic and cured by the following: In a half cupful of water rub the horn of some kind of a serpent against a piece of stone harder than the horn; the water turns blue, and the diseased or sufferer drinks this liquid, and is cured. In recent years, brandy, made from mulberry fruit, is also largely used. Its effect is immediate.

6. "*Rheumatism.*—I never saw or heard of a case of rheumatism in Armenia; nor have they any knowledge of *neuralgia.* Opium is applied for toothache, though they are very little troubled with that. As a rule, they have very sound teeth. Why this is so I can not tell.

7. "*Lung diseases.*—A severe cold settled in the lungs is cured by sweating, as follows: Fill an earthen vase with water, close its mouth air-tight, put it in the oven, and boil it for quite a while. Bring the vase out of the oven and put it on one end of the boat-shaped tub, while the person afflicted with cold in lungs, is sitting down on the other end of said tub. The tub is in a very small and closed tent. The sick person now opens the mouth of the vase, and I tell you, Doctor, in about ten minutes the poor fellow is almost dissolved into dewdrops. He is now ready to come out, *but the grandma is not.* He is finally taken out and put in bed and almost smothered. That is the way they treat all for colds.

8. "*Child-birth.*—I suppose their manner of delivery coincides with that of this country as far as the position of mother, while the child is coming out of the womb is concerned. But our women do not suffer near half as much pain. They are not assisted by medical men. They generally have a grandma midwife. In a great many instances they give birth to the child while working in the field all alone. My aunt gave birth to a boy baby on the 7th day of August, while working in the harvest-field; she wrapped it up and walked home with it, a distance of about five miles; in less than a week she resumed her work on the field. I can recall a number of similar cases; so you see they are not confined to bed for any preparation or reparation.

9. "*Ague.*—The ague cures are quite simple and have always been to me interesting; they

are two in number. 1. Take a cup of strong vinegar and boil it; while boiling put in it two teaspoonfuls of pounded coffee and a half teaspoonful of pounded pepper; after these have settled, the diseased one, in the midst of the chills and shaking, drinks it all at once and as warm as he can swallow it, and the ague leaves him for good. I can bear an eye witness to this, having myself suffered very severely from the same disease, and being cured by this same remedy.

"The second method is by the plunging of the sick into cold water all at once. When the diseased is in the most intense degree of chills, calling for all the comforts or covers to be piled on him to keep him warm, then his friends take him by the hands and the legs and plunge him in a trough-full of cold water, and he is relieved.

10. "*Bleeding.*—This is done by cups, leeches and lancet; but leeches are in most frequent use. Leeches are kept for sale by our barbers, in coffee shops, in bottles filled with fresh water; that is, the water is changed every day. The Arabs also travel over the country in selling them.

11. "*Snake-bites.*—A snake bite is nothing uncommon in Armenia. As soon as a person is poisoned by a snake or some other poisonous animal or beast, the people catch a dozen or more frogs, cut them open and apply them one after the other in quick succession on the poisoned or bit spot. In case frogs are not convenient, chickens or lambs are killed and used in the same manner.

12. "*Hydrophobia.*—I cannot give a reliable answer to this, but I have seen tobacco used for the fresh bite of dog.

13. "*Hemorrhage.*—Salt water is the only remedy I can recall used to stop hemorrhage.

14. "*Freezing.*—I suppose you are aware that the climate is very severe in Armenia in winter, hence the cases of persons found frozen or almost so, are of common occurrence. You remember how the ten thousand Greeks froze to death in Armenia. When the person is only half frozen or frozen on his feet, he is put in a pile of cattle manure and kept there until he returns to his senses.

"I also remember seeing the juice of some kind of plant used for weak eyes and earache; also the root of some wild flower for moving bowels, but I cannot recall their names, nor have I seen them in this country.

"I hope these facts will be satisfactory, as all that I have mentioned are reliable and true.

"Thanking you for your kindness shown me while with you, and also for your kind invitation to your pleasant home, I am, with best wishes and kind remembrances,

"Sincerely yours,

"N. A. Morjickian."

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, March 14, 1888.

The Vice-President, W. W. Keen, M.D., in the chair.

Dr. J. Madison Taylor, read a paper on the

Early Recognition of Exophthalmic Goitre (Graves' Disease).

In the paper which I have the honor to read to you to-night, I shall not attempt to do more than call your attention to the importance of early recognizing a disorder which often eludes one, to point out certain features which should enable us to do so, and to offer in illustration, very briefly, the salient points in half a score of cases.

Exophthalmic goitre, or Graves' disease, is not a rare malady. At first it is merely a disorder, but frequently becomes a serious disease, and is known to cause death. More often it unfits its victim for active usefulness, or, at least, limits this and sadly disfigures him. Like certain other ailments the outcome of irregular nervous discharge, what in its incipiency is a very manageable complaint, produces in time a disastrous effect upon the tissues, and forms a practically unconquerable disease. Dr. Jonathan Hutchinson says: "Graves' disease appears to me to be of the utmost importance, not only on its own account, but as what we might call a type malady. It is the most definite and striking example of which we know, of a severe and protracted malady which, despite its severity and persistence, yet has a natural tendency to recovery."

In reviewing a large number of cases in the search for a complete symptomatic picture, I find that the most constant early feature is sudden and marked evidence of loss of nervous equilibrium. The vaso-motor nerves seem quite unstrung. Hence arise flushing, sweating and other skin changes, diarrhœa and transient albuminuria. If at this time a careful watch be kept, I think we should find irregularities in the action of the pupil. The skin usually loses its healthy hue, grows sallow or dark, and becomes greasy to sight and touch. This oily look was present in

most of the cases I have seen, though I have not seen it mentioned elsewhere. Begbie recounts one case of pigmentation, or bronzing, of the skin; Reynaud calls attention to vitiligo; and Edward Squire, to a discoloration in an isolated instance. The oleaginous appearance seems to me quite constant on face and body. This grows less when salt sponging and belladonna form part of the treatment.

Gowers calls attention to muscular tremor. I have seen this rarely. In cases III and V there is a tremulousness in the voice, which I ascribe to nervousness; yet it is constant. The emotions become often so overwrought that various mental peculiarities excite apprehension. Or a wiser person may regard the case as one of pronounced hysteria; and, indeed, all through the malady hysteria remains present, more or less, leaving one not seldom in grave doubt. Frequently delusions occur, and these so closely in unison with the ordinary habits and thoughts of the individual as to render them most difficult of detection (see Case VI).

Dr. Hilton Fagge warns us to be on the lookout for "slight cases in which one or two of the cardinal symptoms may be absent throughout." Trousseau also insisted on this point. Von Graefe expresses the opinion that among women it is not rare to find instances of this malady where the only symptoms are disordered action of the heart, not accompanied by valvular trouble or hypertrophy, nor the faulty action of the lid as described by him.

Heart disturbance most often leads the sufferer first to seek medical advice. The pulse is always quick and irritable, usually intermittent. The heart-beats, as a rule, bear surprising relationships to the pulse. Overaction of the heart is well known to be a frequent feature of anæmia and chlorosis. Begbie thinks it a powerful factor in causing Graves' disease. Ross regards the anæmia which is usually present as rather a result. Throughout the whole vascular system there is a manifest lack of *tone*. So constant is this that it may yet be found competent to explain the causation of the disorder. Certainly the graver features bear causal relation to this state. The vaso-motor nerves seem all out of balance; nor can it be confined to one part, though the cervical sympathetic is most prominently involved. There are cases in which limited areas not governed by the upper ganglia show derangement, as in a woman now under the care of my friend, Dr. E. T. Bruen, where one side sweats from shoulder to toe, and the opposite eye is prominent. Arterial tension varies rapidly, and unaccountably; hence the oft complained of noises in the head, amounting at times to terrific roarings (as in Case V). This may explain the maniacal attacks, as well as blood-spitting, thirst, and transient albuminuria.

The heart itself is rarely diseased. The overaction in time brings on hypertrophy; more commonly, dilatation. It also suffers from the general malnutrition which is noticeable throughout the circulatory system. The small amount of structural damage which this viscus sustains is a matter for remark, however, when the profound functional disturbance is considered. Systolic bruits are commonly heard, even over the auricles and the great vessels of the neck. Dyspnœa is distressing. This at times, even early in the history, alarms one who feels naught else to complain of. The thyroid enlargement is liable to appear long before the eyes become prominent, but readily escapes attention. It may happen that a sense of constriction is felt when swallowing, especially in men who wear tightly fitting collars. Both lobes are, as a rule, enlarged; but if only one, it is generally the right. When recovery takes place, this badge remains to chronicle the victory.

The eye prominence is late to appear, as a rule, and it would seem to mark the height of the disorder. Before the exophthalmos, there may generally be noted the sign asserted by von Graefe to be pathognomonic, a belated action of the lid in following a downward movement of the ball. Sometimes the lower lid is tardy in following an up glance. This obtrusion of the eyeball is the most picturesque feature, but happily it is not constant, and is often very late. It is of both eyes, mostly, but if of only one, again the right suffers. Sight is seldom affected, except where the outstanding, unprotected cornea suffers hurt or irritation; then opacities may result. If errors of accommodation exist, this correction, in my opinion, greatly aids in reducing the exophthalmos. Fundus lesions are not characteristic; though pulsation of retinal vessels may serve to confirm suspicions.

Knee-jerks are rarely abnormal; often in slight excess. Electrical examination has been, very recently, shown by Charcot, and confirmed by Vigoroux and Norris Wolfenden, to aid greatly in fortelling the onset of this trouble, the bodily resistance being greatly lessened most peculiarly in this disease. This may prove a valuable aid in diagnosis.

Case I.—This illustrates extremely well the more distinctive features other than

exophthalmos, which is not present—especially the marked vaso-motor disturbance.

Jennie H., aged twenty-three years, single; no neurotic history, intelligent, hopeful temperament; somewhat emotional and talkative. Vague history of a fall at two and a half years, followed by a convulsion, and, from time to time, "fits" are described, but not clearly. At first they seem to have been epileptiform, but later resemble emotional overflow. At fourteen years had typhoid fever, and for twelve months was "weakly." Some swelling of the limbs noticed—then came a period of good health. At seventeen years menstruated first, but not regularly for a year or more. At nineteen years began to work in a shoe factory, in a very exposed room, excessively cold in winter; frequently sat in wet shoes all day long. At twenty years, after a very painful day from cold, walked home in slush, profoundly exhausted; soaked her feet in hot water and went to bed. Then followed a nervous chill with throbbing pain at heart—it beat rapidly; an overwhelming sense of suffocation arose. From that moment the heart has been disordered. Then followed a series of medical pilgrimages to different dispensaries, with small benefit.

I think many of her symptoms were, even then, hysterical, masking effectually her real trouble. She had hæmoptysis, cough, great emaciation, and was treated for phthisis. The fits brought her under treatment for epilepsy. So far as I can learn, no one noticed anything amiss with the eyes or neck. I think there has been at no time exophthalmos, but a peculiar fluctuation in the condition of the pupils, which I infer is not recent. The dyspnœa grew worse steadily, till it became impossible to lie in bed; and for six or eight months she slept fitfully propped up in a chair. In May last a profuse blood-spitting prostrated her for four weeks; soon after the urine was suppressed for three days, with no pain—then a very dark, thick, offensive fluid passed. During the past summer was very weak and thin, but attempted repeatedly to work. Over-exertion at the wash-tub bowled her over again; several hemorrhages followed, and on October 1 she applied to me at the Howard Hospital.

I found a very pale, thin woman, suffering great dyspnœa; respiration 24; pulse fairly regular, 130 to 135; coughing incessantly; carotids throbbing wildly; pupils widely dilated; von Graefe's sign absent. There was complete mydriasis, as we found later, but no fundus lesion. The heart was laboring, loud musical murmur over base; apex beat downward and outward; *bruit de diable* in vessels of neck; thyroid gland enlarged, especially to right side, conveying thrill to hand; neck fourteen and three-quarters inches; skin pale and oily looking, readily sweated, and became chilly; legs œdematous; menstruation had been absent for three years; bowels always loose; urine, small amount, bright red with blood; sp. gr. 1.009; no casts; knee-jerks excessive in both legs; station bad from weakness.

Treatment.—The treatment consisted of carefully regulated feeding and rest; to drink plentifully of flaxseed tea; iron, in form of Basham's mixture, and digitalis, and hot hip-baths; belladonna plasters to the over-excited heart; later, cod oil and bromides, with digitalis. In a week the pupils became responsive to light; cough greatly moderated; the urine only smoky; heart sounds more defined.

To be brief, in two months the cough ceased; she could lie comfortably in bed; ate well and slept well; pupils became normal; had two or three "spells"—a little scolding aided these. In six months the girl pronounced herself cured, but she is readily upset by trivialities; twice the pupils have widely dilated on catching a slight cold, and once recently the urine showed traces of albumin. The menstruation was established twice, and slight showing at other times. She can now work at house chores with small fatigue. Pulse about 85 to 95, when standing.

Case II.—Mrs. H., aged about twenty-eight, no neurotic history, two living children, came under my care in 1881 during a miscarriage with adherent placenta. A similar disaster had occurred also some months before. My attention was drawn to a most disfiguring degree of exophthalmos. This had been observed within a few months by a well-known physician, who also warned her that she could scarcely hope again to bear a living child—probably on account of the disorder thus indicated. There was then menstrual derangement and great dyspnœa. Digitalis and ergot were ordered, also care to avoid exertion, but no clearly defined schedule of living. This I supplied and rigidly enforced—insisting upon systematic feeding and rest. I also found an irritable pulse and temper, muffled heart sounds, etc., but very slight right thyroid enlargement, a markedly livid oily skin, sweating surface, loose bowels, and occasional albuminuria.

Under treatment consisting, as stated, of regulated living, digitalis, ergot, along with iron and other tonics, she steadily improved,

till in seven or eight months there remained only dusky skin and the eye and lid symptoms. These last I felt sure would improve under use of glasses rightly adjusted—she having a high degree of myopia. After some persuasion this was accomplished with most admirable results, for the exophthalmos materially lessened thereafter.

I may say, as a matter of interest, that I have since delivered this woman of three healthy children at term, each of which she suckled for a full year, and that she now enjoys excellent health. There is no heart trouble, no goitre.

Case III. Graves' disease; obscure and abrupt cause; extreme nervousness, cardiac distress; death. No autopsy permitted.—Mrs. S., aged thirty-six, no neurotic history, one child. Two years ago she seemed in perfect health, weighed one hundred and sixty pounds. Happily married, surrounded by every luxury and loving care. Sustained no shock, no fright or exhausting disease. Fell into the hands of gynecologists, who found displacements and tears, and repaired these, as it proved none too well. While sitting in perfect health at a theatre, not in the least excited or especially interested in the play, she suffered a nervous chill, and from that time the disorder rapidly grew. The chills frequently recurred, changing to what she described as "waves of feeling up and down the body;" on the slightest exertion sense of constriction in chest, and skin broke into a sweat. Afraid to step about the room. Bowels loose, slept badly, lying awake for hours feeling afraid. The disorder was not recognized.

Sent to Dr. Weir Mitchell with a description of "neurasthenia and heart disease," and through his courtesy I was allowed to see her repeatedly. She was a very excitable, nervous woman, rather thin, weighing one hundred and ten pounds, with a frightened, restless expression. Eyes slightly prominent, some little slowness of upper lid, injection of cornea, tremor in voice, tremulousness of hands on movement, constantly plucking at bed-clothes or handkerchief, or arranging her hair or dress; throbbing carotids, pulse of 125 to 135 lying, and very irregular, loud musical murmur, etc. Bronzed, glistening skin, chilly hands and feet, sweats readily, etc. Thyroid enlarged almost symmetrically, conveying thrill to the hand. Some improvement under rest and tonics. Another operation was found necessary, and though slight, she sank and died. No autopsy allowed.

Case IV. Graves' disease; slight exophthalmos; slight thyroid enlargement; cardiac disturbance; delusions and rapid loss of flesh; caused probably by exhaustion from bearing ten children, and precipitated by sharp dysentery; recovery.—(By permission of Dr. Weir Mitchell and partly under my care.) Mrs. J., aged thirty-nine years, family history good, most favorable surroundings; ten children; began a year ago to lose flesh rapidly during severe dysentery; appetite very poor since. Slight delusions; vertigo. Eyes only noticeably prominent; corneal vessels injected; restless expression; slight tremor; skin clammy and glistening; dyspnœa. Thyroid enlarged a little; heart noisy; no valve defect; very emotional; albumin and muco-pus in urine. Under tonics and rest gained steadily. Referred to me at seashore in summer; rapidly picked up flesh and strength there; gained forty pounds. Now describes herself as being in good health.

Case V. Graves' disease; slight exophthalmos; slight thyroid enlargement; cardiac disturbance and tremor; marked improvement.—Miss R., aged twenty-five, family history good. At ten years had typhoid fever, at eleven very severe dysentery; long in regaining strength; much headache at nineteen years, an illness began by neuralgia in face and marked prostration; noticed rapid breathing; soon eyes were remarked as being "curious looking;" tried to gain strength by exercise in open air. In 1881 again fell ill. In March, 1882, consulted Dr. Seguin, who pronounced unfavorably; at that time had much œdema in legs; ordered digitalis; quiet. Following November grew much better; partly in bed for several months. December, 1883, she saw another physician, who relieved the increasing diarrhœa. May, 1881, to May, 1884, menstruated only once; thence irregular till a year ago, since then fairly regular. Weight about one hundred and thirty-five; skin moist and shiny; beads of sweat on upper lip; tremulous lip and tremor in voice, this seems a constant feature; at times tremor in muscles elsewhere. Exophthalmos slight; von Graefe's sign in both eyes; pupils normal; corneal vessels injected; flushes readily; not pale; heart tumultuous; no valve defect; pulse intermittent, one beat in three or seven, very diffcult to count. Thyroid enlarged symmetrically; well-marked thrill; loud bruit in right neck; buzzing in head; sweats almost constantly; respiration 28, sighing; dyspnœa great on slight exertion; cannot lie in bed at night; bowels loose.

Rapidly improved in most respects under treatment by regulated living, digitalis, and

belladonna; tonics, iron, etc.; salt sponging; hot hip baths; menstruation more comfortable. In January had an attack of nervousness at night time, sense of great pressure in head and flashes of heat over body; ringing in ears. Eyes were examined by Dr. de Schweinitz, who found slight hypermetropic astigmatism; no fundus lesion. Alternate hot and cold water to nape of neck relieved the sounds in head. Is steadily impoving to date.

Case VI.—Miss D., aged twenty-four, family history decidedly neurotic. Mother "queer." At one year scarlet fever followed by "water on the brain;" soon recovered good health. Menstruated at fifteen.

August, 1885. Dysentery.

December, 1885. Heart began to alarm her. Vertigo sitting or walking; grew weak, short of breath, and extremely nervous; could not sleep, began to groan loudly in sleep, which continued till recently. Skin itches intolerably; sweats rapidly on exertion. Roaring noises in the head. Legs swelled, also feet—"the buttons were burst from the shoes."

March, 1886. Neck enlarged. In May the eyes started forward. Appearance: Eyes very prominent, sclerotic shows half an inch or more above and below; lids puffed, corneal vessels injected, face bloated and livid; skin greasy. Thyroid enlarged in three directions, most on the right; neck thirteen and three-quarter inches. Heart sounds clear; impulse heaving; slight systolic whirr. Pulse regular, 112 standing. Bowels very loose; tremulous voice. Eyes examined by Dr. Hansell, show some accommodative defects, but no fundus lesion. Urine albuminous. Decided delusions. No improvement.

Case VII.—Miss M. D., sister to above, well-grown girl, well till a year ago, when she had "walking typhoid"; afterward very weak; fainting spells; vertigo on walking; sweats readily; constantly chilly, especially the hands and feet. Buzzing in the ears. Menstruated at thirteen, but it is extremely irregular, rarely lasting over two days. Eyes showed no lid sign; no exophthalmos. Thyroid enlargement right; neck twelve and three-quarters inches. Heart quick and feeble; muffled sounds, roaring noise over the right clavicle and through the thyroid, also marked thrill. Carotids pulsating visibly. Pulse, 128 to 130. Very pale. Is improving.

Case VIII.—Mrs. S., aged forty-six; mother living, a "fidgety" woman, has two children. Fairly good health till 1881, when she had typhoid fever, followed by large abscess in the abdomen, opened in two places. Treated in the Jewish Hospital. After this shortness of breath began. In 1881 a financial blow greatly worried her; she would sit and brood over her troubles, then the fever. Exophthalmos began, along with diarrhœa; sweated a great deal on both sides. Buzzing in the ears. Appearance: Strongly built woman, weight 130 pounds; skin muddy and dusky. Left eye very prominent, right less so; lid signs of both eyes. Carotids throb moderately. Heart sounds clear and distinct; slight bruit. Has been under treatment for eight or nine months. Digitalis and iron and belladonna. Dyspnœa greatest on cold days. Urine at times profuse; no albumin. Œdema of legs fluctuates. Is steadily recovering, though susceptible to fatigue, cold, and shocks.

I hope to discuss the treatment, on which I have some decided opinions, on another occasion. This consists mainly of rest, judicious feeding, tonics, and carefully selected sedative measures.

Competent glasses, too, are essential; at times sharp counter-irritation; especially diuretic remedies and attention to the emunctories. Galvanism, too, has immense value in some instances, but requires judgment in selection of cases.

In brief, whatever measures tend to repair the tone of the vascular system, and allay nervous excitability will best bring about gratifying results.

In opening the discussion Dr. S. D. Risley said: I would like to ask Dr. Taylor whether there is any indication by which the development of exophthalmos can be expected in cases in which it has not yet appeared.

Dr. J. B. Roberts: I believe that the great ocular deformity which is so unpleasant to the patient, and attracts so much attention, can be remedied by a very simple operation: merely putting a stitch at the outer canthus, after freshening the edges of the lids, to diminish the optic commissure after the case has made such progress that it is reasonably certain there is to be no further diminution of the prominence of the eyeballs. The patient can be made more comfortable and less conspicuous.

Dr. Edward Jackson: The procedure suggested by Dr. Roberts might be resorted to for other than cosmetic reasons. I recently saw a case of this disease with very great exophthalmos, in which one eye had been lost through sloughing of the cornea due to exposure; and I afterward learned that the second eye had been lost in the same way.

Such an accident might be prevented by narrowing the fissure of the lids.

Dr. A. V. Meigs: I know of one person who has completely recovered from this disease, a woman who had a very severe attack many years ago, under the care of my father. The prominence of the eyes, which was very great, is now hardly noticeable, and yet no operation was ever done. I do not think much would be gained by sewing up the canthus, for while the disease is in its acute stage, it is hardly likely the operation would afford much relief, and later, if the patient recovers at all, the difficulty cures itself. I think I know the case Dr. Roberts had in his mind when he spoke, and Dr. de Schweinitz, who has seen the woman in question, will probably agree with me that nothing would be gained by an operation. One thing I have learned of recent years, and it is that it is not necessary in all cases to put the patient in bed. I could mention three or four cases I have successfully treated with tonics and proper regimen, without its becoming necessary to have rest in bed; the cases, to be sure, were not severe. Dr. Taylor speaks of the early recognition of the disease. For my own part, I do not see how a positive diagnosis can be made until we have at least two of the features of the disease present, namely, the cardiac palpitation and some thyroid enlargement; the prominence of the eyes occasionally does not manifest itself, but a diagnosis can undoubtedly be made in its absence.

Dr. G. E. de Schweinitz: I have examined the case that Dr. Meigs refers to, and I saw nothing to be gained by surgery. The eyes were at first very prominent, but they were then receding, and now the normal relation of lids to eyeballs is restored. Inasmuch as there was considerable myopia, and hence the not uncommon prominence of myopic eyes to begin with, they will always be more or less conspicuous.

Dr. S. Solis-Cohen: I have been extremely interested in this valuable paper of Dr. Taylor's, the more so that I think I recognize in his first case a patient whom I have seen, but in whom I did not recognize this disease. She was treated at the Jefferson Hospital some three years ago for anæmia, and was apparently cured. A year ago she returned with the history of "fits" spoken of by Dr. Taylor, and was irregular in attendance and unreliable in statement; the hysterical element so noticeable, probably preventing the careful investigation the case should have received. I consider it the more remarkable that thyroid enlargement should have escaped notice at the clinic in this case, as the comparatively frequent discovery of it at one time, in cases of cardiac and vaso-motor disturbance, has put all the clinical assistants on the lookout for the phenomenon. I can thoroughly agree with Dr. Taylor that vaso-motor paresis plays an important part in the development, if not in the genesis, of this disease. The only case I have seen in the male subject occurred in a young man subject to frequent attacks of flushing of the face, sometimes accompanied with high temperature, in whom the rapidity of the heart's action had led to a diagnosis of hypertrophy of the heart, not warranted by physical exploration. The eyes were not involved at the last time I saw the patient, nor was thyroid enlargement sufficient to attract attention without special examination. I have now under my care in private practice a young lady not at all hysterical, subject to similar attacks of flushing which sometimes leave behind for a short time wheals like those of urticaria. She has also had two attacks of sudden transient blindness, after which all that could be detected in the fundus was moderate congestion. This patient's cardiac action, rapid and irregular at these times, is at other times perfectly normal. No organic lesion of any kind has been detected either by me or by more competent observers. It is possible that this may be an early stage of Graves' disease. Improvement has taken place under minute doses of picrotoxin, a drug which Dr. Bartholow has prescribed in cases of exophthalmic goitre, at the hospital, with very good results. One case especially I recall which was associated with purpura. I would like to know whether Dr. Taylor has met with this association. A very interesting case of acute exophthalmic goitre presented at the clinic, which Dr. J. C. Wilson may remember as the subject of one of his clinical lectures: an anæmic young girl affected from childhood with nystagmus, in whom goitre and exophthalmos were asserted to have developed within a short time after a fall from a ladder. She was unable to button her collar, which friends had opened in attending to her after the accident.

Dr. J. C. Wilson recalled the case mentioned by Dr. Cohen, but not with sufficient distinctness to add anything of importance to the account already given. Dr. Wilson briefly narrated two cases of Graves' disease, recently seen in his private practice, in which the symptoms developed rapidly after mental shock. The patients were young women. The first, a servant, aged twenty-four, of previous good character, was engaged to be married to a young man who was by occupation the driver of an ice cart. Within a day

or two of a visit to her, he was accidentally killed, and her first knowledge of his death came through the newspapers. Cardiac overaction at once developed, and within a month thyroid enlargement, and slight exophthalmos. Under rest and large doses of Fowler's solution complete recovery took place in a year. The second case was that of a lady, aged twenty, who rapidly developed the characteristic symptoms of Graves' disease after the shock and grief occasioned by the disappearance of a near and loved relative, and the discovery that he was a defaulter to a very large extent. The prominence of the eyeballs was in this case very slight; the other symptoms were characteristic. Under treatment by rest and arsenic decided improvement took place. It is now a month since she last reported.

Dr. Taylor: In reply to Dr. Risley's query, Does any sign clearly foreshadow the exophthalmos? I can only say that I know of none, nor did I see anything in the literature of the subject to aid us. It usually marks the height of the disorder, though this may be the first feature noticed, especially when it arises suddenly as from shock or overwrought emotion.

To Dr. Meigs' objection that the three classical symptoms can alone and in conjunction constitute the disease, I can only say that it seems to me readily possible to recognize in the peculiar vaso-motor disturbances the extreme and unaccountable nervous excitability, the appearances of the skin, etc., the early stages of this disorder. In fact, the object of my paper was to call attention to this very possibility, so that a quietus might be placed upon it at the very beginning, if possible.

In the use of galvanism we have a valuable aid in diagnosis, as Charcot and Vigoroux have pointed out, but in the treatment it has not been of greater use than some other measures, though it should always be used in the severer cases. Many of my own patients live out of town, but upon those in reach I use it.

In my endeavor to be brief I did not intend to say much on plans of treatment, leaving that for consideration elsewhere, but rather to speak of early recognition and *early* treatment, which should consist of rest, carefully regulated living, food, and tonics.

In opening the discussion, Dr. Thomas's paper on

Graduated Tenotomy in the Treatment of Insufficiencies of the Ocular Muscles (Stevens's Operation),[1]

Dr. H. F. Hansell said: I would like to ask Dr. Thomas for a more definite statement as to the means of diagnosis. To my mind these are not at all satisfactory. The recognition and the exact determination of superior and inferior insufficiences are very difficult, much more so, than of lateral defects.

Dr. B. Alex. Randall: I have for years taken great interest in the subject of muscular insufficiency, the more so because I have myself been troubled with a defect of the kind, which Dr. Risley corrected for me ten years ago; and with his kind aid, and independently, I have been studying the matter since. As to diagnosis, much has been written, sometimes pretty wide of the mark; and I cannot see that Dr. Stevens has improved our methods. He has brought forward a very nice set of terms for what we have long known, and he has expressed clear-cut opinions which read well. In the same way, Landolt makes out very pretty graphic charts of cases, and marks out well defined groups, which are to be treated according to certain rules. But the cases which I meet in practice refuse very often to be included in such categories, and very dissimilar cases afford discouragingly similar charts.

I understand from Dr. Thomas's paper that the estimation of defects is largely made with a distant object, presumably a light at twenty feet. To do this we must know the refraction and the accommodation, and I suppose that these are investigated as a matter of course. But it is not safe to take the accommodation for granted. I can myself change my exophoria to apparent esophoria by the accommodative effort, so-called; and every patient may as readily do the same.

As to correction by operation, I cannot speak like Dr. Thomas from personal experience. We all know that when a certain degree of error is reached it is necessary to operate, and Dr. Stevens places that point very low. His method of operating is highly praised as a delicate one, but the necessity of dividing the operation into many steps is rather unfortunate. However, if he can thus relieve epilepsy, that minor disadvantage may be overlooked. It may be said in conclusion, that except in pointing out that *hyperphoria* is a frequent cause of perplexing and irregular insufficiencies of the lateral muscles (?), Dr. Stevens has added little to our knowledge of the nature of these affections; that in his claims as to their importance, he has gone much further than the experience of equally competent and diligent investigators has enabled them to confirm him; and that in his operative treatment he has merely developed a refinement of the partial tenotomy long in

[1] See page 460.

use, as the only means of correcting without overdoing it, the minute deviations from the perfect balance which he deems worthy of operative interference.

Dr. Thomas: Lack of time prevented me from treating at length in the paper of the points as to diagnosis which have been made the subject of questions. There is a variability, and yet, after all, a certainty in these tests which comes as the result of practice and observation. There is an irregularity in the results of the tests from day to day, but after getting the extreme limits of the swing and studying all the circumstances of the case, one is able to strike an average which very fairly represents the error to be corrected. Then a prism is temporarily adjusted to compensate for this error; and thus we make a crucial experiment and are further guided by the effects obtained. A lighted candle at twenty feet, and the dot and line of von Graefe at reading distance, are *both* to be employed as test objects, and a comparative study should be made of the results obtained—both in the absence and in the presence of accommodation. In this way we frequently get important clews. Sometimes anomalies appear in the action of the lateral muscles comparing the tests at reading distance with those at twenty feet; and when great erraticism of this sort is shown, we may be pretty sure in the majority of cases that we shall in the end find a manifested hyperphoria. Unfortunately, there is no known analogue of the mydriatics which we can well use in these cases, and yet with great patience and watchfulness we shall usually succeed. My results are hopeful in epilepsy, but my operations are too recent to speak positively of cure.

In reply to a question by Dr. Osler, Dr. Thomas said that he had not as yet met with any case of chorea suitable for the operation.

Hospital Notes.

PHILADELPHIA LYING-IN CHARITY.

TREATMENT OF MAMMARY ABSCESS.

Reported by Chas. P. Noble, M.D., Senior Assistant Physician.

From the therapeutic standpoint, mammary abscesses may be divided into those of recent formation and those of longer duration. The treatment of recent cases, those in which the abscess has not discharged, is similar, whether sub-dermal, parenchymatous or sub-mammary. The sub-dermal abscesses, usually connected with Montgomery's glands, are generally trivial, and would doubtless heal after incision without special precaution. It is more than questionable whether sub-mammary abscesses are not simply parenchymatous abscesses where the pus has burrowed posteriorly in seeking an outlet. So that practically we have the parenchymatous abscess to deal with. The indications are to evacuate the pus and promote the healing of the cavity. These are met by an incision sufficient for drainage, with the antiseptic dressing. The incision and manipulations are so painful that ether is required. The service at the Charity has afforded but few cases of this class, and these, with but one exception, were outside cases. This woman was syphilitic and septic. In the maternity wards strict prophylaxis is maintained, with the above happy result. The operation is done as follows: After etherization, the breast and surrounding parts are scrubbed with soap and water, and then disinfected with sublimate solution (1–2000). A radial incision one-half inch long is made down to the abscess. If the amount of pus is small, and seems to be thoroughly evacuated, the cavity is irrigated with the sublimate solution and the dressing applied. Otherwise the finger is introduced, neighboring abscesses, if any, are opened, necrotic septa broken down, and the necrotic masses thoroughly removed by irrigation. Large cavities with communicating sinuses are packed with sublimate gauze; in moderate sized cavities the drainage-tube is used. The dressing consists of sublimate gauze, absorbent cotton and the roller bandage. In the milder cases redressing is not practiced for several days, without special indications; in the others, after twenty-four or thirty-six hours. Then the packing is removed, irrigation practiced, the tube or a smaller amount of gauze inserted, and the dressings reapplied. The process is repeated when the discharges soak through the dressings. Healing has been rapid and without incident.

In the cases of longer duration the condition is usually one of mammary fistulæ with recurrent abscess formation. The so-called pyogenic membrane is present. Several cases with extensive sloughing (one during pregnancy) have been under care. The same operative technique is observed. The incision, or incisions, are frequently extensive, the radial direction being observed as nearly as possible to avoid cutting across the milk-ducts. The neighboring abscesses are carefully opened; the partition walls broken down with the finger, or incised; the walls of the sinuses and abscesses scraped with the finger or cu-

rette; and the whole disinfected with sublimate solution, and the detritus removed with the irrigator. The operation is sometimes extensive, and the amount of blood lost considerable. In these cases sutures are introduced whenever primary union can be gotten or contraction favored. Equable pressure, secured by cotton and the bandage, greatly favors closure of these cavities. The drainage-tube and gauze packing are used, and the after-treatment is similar to that described. In no case has there been a failure to obtain a cure, in some brilliant results were attained, and in general the healing process was steady and progressive. In some cases granulation was stimulated by the occasional use of silver nitrate. Sublimate irrigation favors granulation. Nursing from the affected breast is suspended, and the patient confined to bed until the healing process is far advanced. The essentials aimed at in this method are thorough opening and evacuation of all pus sacs, thorough drainage, and thorough antisepsis, together with the enforcement of perfect rest. The method is based on that of Billroth, and is, indeed, but the application of general surgical and Listerian principles.

Periscope.

Anomalies of the Genital Organs in Idiots and Epileptics.

In the *Progrès Médical*, February 18, 1888, Bourneville and Sollier communicate the results of their personal study of the genital organs of 728 idiots, or epileptics who were more or less imbecile or demented. They give elaborate tabulated statements of these cases, and sum up the results of their observations in the following statements:

1. In the first place, it is obvious that idiots and debilitated epileptics present anomalies with extreme frequency as compared with sane people. 2. Those who have become epileptic at a certain age, and after being partially developed, present much fewer anomalies than the simple idiots. Their genesic functions, unhappily, seem less affected than in the latter, if one may judge by the fewer number of cases of concealed testicle. 3. Atrophy of the testicle seems to affect the right side nearly as frequently as the left, although it is a little more frequent on the latter—a statement which confirms the general opinion of authors. 4. The physical and intellectual degeneracy produced by epilepsy seems to have a definite influence upon the production of varicocele, for idiots who are non-epileptic, do not, so to say, present it. 5. When epilepsy seizes upon a child at the beginning of its life, it produces throughout its being an arrest of development which is much more marked than when epilepsy occurs in adolescence, and this arrest of development, while appreciable upon the whole of the individual, is most characteristic in the genital organs. 6. Idiots, epileptic or non-epileptic, frequently present a particular form of the penis, called bell-clapper or club-like. This shape is not acquired by masturbation, as certain of those who present it have never been addicted to masturbation.

The Etiology of Phthisis.

Dr. R. W. Philip, Physician to the Victoria Dispensary for Consumption and Diseases of the Chest, Edinburgh, in a communication upon the Etiology of Phthisis to the *British Med. Journal*, January 28, 1888, says, in conclusion: 1. In view of the work of Koch, it is impossible to avoid admitting that a causal relationship exists between the tubercle bacillus and the phthisical process. 2. The mere predication of this relationship is not sufficient in explanation of the clinical facts and the generally fatal termination of such cases. 3. The usually received explanations of the *modus moriendi* in phthisis are insufficient. 4. It appears probable that the lethal influence of the bacillus is due to the production thereby of certain poisonous products. 5. Clinical and experimental evidence appears to indicate that the morbid secretions from the respiratory surfaces afford a good medium for the growth of the tubercle bacillus, and, presumably, for the elaboration of such products. 6. Such a product is separable from the carefully selected and prepared sputum. 7. This product is possessed of well-marked physiological properties, being eminently toxic to frogs, mice, and other animals. 8. The toxic properties of the product are, generally speaking, depressant. 9. More particularly they include a marked depressant influence on the heart. 10. This depressant influence seems to be exerted through the medium of the cardio-inhibitory mechanism. 11. The toxic action of the product is more or less completely opposed by atropine. 12. The amount of the product which may be separated appears to bear a distinct relation to the abundance of the bacillar elements present. 13. Absorption of the poisonous product most probably occurs by way of the lymphatic circulation.

Black Tongue.

In the *Münchener med. Wochenschrift*, No. 14, 1887, Schech describes under the name "black tongue" a condition of the tongue which occurs without subjective symptoms and in which the coloration is not due to ingested coloring matter. The color is a more or less pronounced darkish or blackish brown, even blackish blue. Only at times is there a feeling of dryness, or a bad odor. The coloration begins for the most part immediately in front of the circumvallate papillæ, on one or both sides, and extends to the point of the tongue. The latter and the borders of the tongue are, in the meantime, nearly always normal. The affected parts seem rougher than the ordinary condition, and are set with longer or shorter fibres. This affection has been regarded as parasitic, and Dessois has given the name "glossophyton" to the fungus found in it. Schech, however, looks upon these fibres as excessively enlarged, pigmented and horny filiform papillæ. The cause has been referred to the smoking and chewing of tobacco, but probably this is a mistake. Treatment is unnecessary, as the affection causes no trouble. Weak alkaline mouth-washes are lauded; and, in case of necessity, mechanical removal of the fibres is recommended.

Ascending Paralysis after Whooping-Cough.

P. J. Moebius reports to the *Centralblatt für Nervenheilkunde*, 1887, No. 5, a case of paresis which developed in conjunction with whooping-cough. The patient was a child, three years old, and the paresis affected first the limbs, then the arms, the throat muscles and the diaphragm. Tendon reflexes were absent; but there was no disturbance in sensibility, no change of the electrical excitability, and no atrophy. After the paralysis had persisted several weeks, recovery occurred. The author believes that the disease is to be referred to an affection of the peripheral nerves—a multiple neuritis; he is inclined to regard it as a nervous sequela of whooping-cough, and as analogous to the post-diphtheritic paralyses.—*Centralblatt f. d. med. Wissensch.*, Dec. 10, 1887.

Sewage Farming in France.

The project to utilize the sewage of Paris in the lower part of the forest of St. Germain has been ratified by the French Chamber, notwithstanding the opposition of the residents of that district, who fail to see, in the more prolific growth of cabbages and other edible vegetables, an adequate compensation for the almost inevitable inconveniences of the system. Victor Hugo's remarks upon the wastefulness of the present system of sewage disposal in his well-known work, *Les Misérables*, will not have been merely interesting if they have aided in bringing public opinion around to his views. It was urged that over $5,000,000 was lost annually to agriculture by not consigning sewage to its natural destination—the soil—but all such estimates must be taken *cum grano salis*, seeing that in this country, where the system has been carried out on a very large scale, and on the most scientific principles, the authorities consider themselves very fortunate if they succeed in covering their expenses—a result indeed which is seldom attained. If the scheme prove satisfactory—and there is no reason why, with certain restrictions it should not be so—the present system of scavenging in Paris will be abolished.—*Medical Press and Circular*, February 15, 1888.

Terpin Hydrate.

In a communication on terebinthinates to the *Lancet*, March 10, 1888, Dr. Prosser James says that terpin hydrate has only a slight taste, is rather insoluble, has no odor, and is solid. It may be seen as small needles when it spontaneously crystallizes from a mixture of turpentine and water, or may be obtained in large rhombic crystals by allowing alcohol (three parts), turpentine (four), and nitric acid (one) to stand in shallow dishes three or four days. It is dissolved in only small proportion by cold water or turpentine, but is taken up more readily by hot water, alcohol and ether. For this reason it is best given in pills or wafer paper. For small doses pills containing two grains each are convenient, and one can be taken every three or four hours. For larger doses, which should not be repeated so frequently, wafer paper is better. An emulsion may also be made, but this is not an agreeable method. The hydrate may, however, be dissolved in warm glycerine, and after solution an equal quantity of some syrup may be added. It is well to begin first with small doses, as these are sufficient to act upon the bronchial mucous membrane and also to affect the kidneys. It will be found useful in restraining the cough and secretion of bronchitis, and in stimulating the membrane to more healthy action, perhaps also disinfecting the sputa. Germain Sée has also found that full doses restrain the copious sputa of some cases of phthisis, and he met with no gastric irritation after long continuance of the drug; but others have not been

equally fortunate. In some instances small doses seem to increase bronchial secretion. It has also been employed successfully in hæmoptysis.

Simple Ulcer of the Duodenum.

The practical conclusions of Dr. Bucquoy's recent publication upon a clinical study of simple ulcer of the duodenum, are thus stated in the *Gazette Médicale de Paris*, Jan. 28, 1888: Without doubt the disease has a latent character, which renders the diagnosis difficult, but it presents some symptoms which permit us to determine the existence of the duodenal lesion. Its symptoms are: 1. Intestinal hemorrhages or black vomit, beginning abruptly, occurring at times in the midst of apparent perfect health, without serious consequences, but, later, repeating themselves several days, with more or less intensity, in such a way as to compromise the life of the patients. 2. A pain, existing nearly always in the region corresponding to the inferior surface of the liver, a little to the right of the linea alba. 3. Some digestive troubles, or extremely violent attacks of colic, manifesting themselves ordinarily three or four hours after the ingestion of food. 4. Termination by perforation of the duodenum, followed by fatal peritonitis, or by repeated or alarming hemorrhages.

Rare Case of Acute Iodism.

In the *Wiener med. Presse*, No. 28, 1887, F. Heller reports the case of a man, 30 years old, who became salivated following a short course of treatment with mercury for a primary syphilitic sore. He was ordered:

℞ Potassii iodidi.....3j
Aquæ destillat.....f℥ij
Syrupi cinnamomi.....f℥iij
Mix. Sig.—Tablespoonful 3 times a day.

After the very first spoonful the patient felt a strong burning in the mouth, and soon great itching of the surface of the body, headache, violent pains in the fingers, benumbing of sensibility, feeling of dryness and irritation in the throat, and difficulty in swallowing. After a second tablespoonful of the medicine these symptoms were increased and there appeared on the palmar surfaces of both hands, and particularly of the fingers, small red, somewhat elevated maculæ, which were due to effusion of blood and were extremely painful. Then coryza, conjunctivitis, and flushing of the face also occurred. The pulse was about 100, the appetite not much affected. In spite of discontinuance of the drug the symptoms kept up for two days. The spots were then of a rusty-brown, painless and no longer elevated, and after eight days the iodism disappeared. The patient had some years before manifested a tendency to skin diseases, especially of a hemorrhagic kind.—*Centralblatt f. d. med. Wissensch.*, January 7, 1888.

Treatment of Puerperal Sepsis with Salicylate of Sodium and Alcoholics.

Von Jaksch, of Gratz, in a comprehensive article in the *Wiener med. Presse*, No. 1, 1888, speaks in the most positive terms of the value in puerperal sepsis of salicylate of soda in combination with alcoholics. His opinions are based upon fifty cases treated in the wards of Nothnagel, in Vienna, under von Jaksch's personal supervision. He began the administration of the drug by giving seven and a half grains of salicylate of sodium hourly until the temperature fell to normal, a result generally obtained in fifteen to twenty hours. Symptoms of intoxication were rarely observed; when they appeared in force the dose was reduced one-half. He considers symptoms of intoxication no reason for abandoning the treatment, and after four or five hours he was generally able to resume the original doses. In conjunction with this treatment he employs alcoholics in full doses, cognac, sherry, and any form of good wine being freely given, with the best possible diet. In the event of heart failure becoming imminent, hypodermic injections of camphorated oil and other cardiac stimulants were given. If five or six doses of seven and a half grains of the salicylate produce no effect, von Jaksch does not hesitate to give fifteen grains hourly, and considers the administration of four and a half to five drachms of sodium salicylate in twenty-four hours fully indicated in severe conditions. The only ill effect he has seen follow this treatment is mild delirium.

Von Jaksch is not prepared to assign to sodium salicylate a specific action upon puerperal sepsis, but he desires to call the attention of those who treat large numbers of puerperal women to its use, and he advises, in cases in which a moderate rise of temperature occurs *post-partum*, that the drug be given promptly, sixty to seventy-five grains daily, and if severer symptoms follow the full doses, he would administer the remedy, in doses of from forty-five to sixty grains daily, to pregnant women just before labor, when the surroundings are very unfavorable and non-hygienic.—*American Journal of the Medical Sciences*, March, 1888.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium,	**6.00**
Physician's Daily Pocket Record,	**1.25**
Reporter and Pocket Record,	**6.00**
Reporter, Compendium and Pocket Record.	**7.00**

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

STANDING OF THE PHYSICIAN IN THE COMMUNITY.

In a recent issue of *Truth*, MR. LABOUCHERE, its brilliant and somewhat opinionated editor, takes an English physician named Allan to task for having refused to attend a woman in confinement until he had been paid a guinea in advance for his services. During the delay incident to the woman's husband's securing the required guinea, his wife died. About the same time the *Medical Press and Circular* contained a letter from a physician, who complained because he was accused of having caused the death of a child with diphtheria, whom he attended, and upon whom he performed tracheotomy, actually sucking out the obstruction in the tracheotomy tube when it became clogged. He left his little patient doing well, with instructions to the parents to clear the tube in a like manner, if it became clogged again. These instructions were not carried out when the difficulty recurred, and the child died. In spite, however, of the physician's unwise zeal for this child's good, he did not escape being accused of having caused the very result he had done so much to avert.

In one of these stories we have an *ex parte* statement by a layman of what seems like heartless behavior on the part of a physician; in the other we have an *ex parte* statement by a physician of what seems like base ingratitude on the part of a layman. Both stories—whatever may be the merits of each case—indicate the unsatisfactory relations often existing between physicians and their patients in Great Britain: a condition which is frequently brought to the attention of the readers of English medical journals. In that country, it appears, medical men are continually struggling against distrust and suspicion, continually striving for an appreciation and recognition which is refused them or extended with apparent reluctance. Such occurrences as we have referred to above are supplemented by a sort of chronic lament from the medical journals that titles are not conferred upon physicians who distinguish themselves by scientific attainments or by the heroic performance of their duty, as they are conferred on men in other walks of life. And, on the other hand, it seems, at this distance, as if the ruling class in England looks upon medical men as belonging to an inferior class, whose effort to rise is too obstrusive and needs to be repressed.

This state of affairs is happily hard to understand in America, where no class in the community enjoys more the confidence and affection of the others. It may be because we have no distinctions which are not open to all who have merit and perseverence, that here the medical man occupies an enviable position in the social world, in the country as well as in the city. Whatever honors the community can bestow are freely bestowed upon physicians in America; and, better than this, the physician here enjoys to a very high degree the heart-felt love of those to whom he ministers. No men in America, we believe, have a more satisfactory lot than the doctors, surrounded by grateful and affectionate friends, and rewarded for their labors by substantial and sentimental returns which leave nothing to be desired. Here, as everywhere, medical men must work hard, and sometimes get no money for their best serv-

ices; but, in the main, they are the recipients of so much kindness that they are thoroughly happy and contented.

This very contentment, the sense of receiving all the appreciation which they deserve, is probably one of the most important reasons why they have so little occasion for discontent. There is no ground for pushing, and the community grants freely what it would, perhaps, never yield on compulsion. So it happens that in America the relations between medical men and their fellow-men are of the most satisfactory character. For this, let us all be duly thankful, and let us all endeavor to continue to enjoy it by continuing to deserve it. It will never cease, so long as medical men look more at what they do than at what they get, and labor—not for praise, but for praise-worthiness.

PRESCRIPTION OF COMMERCIAL FORMULÆ.

In another part of this number of the REPORTER we give space to a notice of an interesting pamphlet by Mr. Emlen Painter, a pharmacist of New York, in regard to the employment by physicians of certain compounds made and sold by manufacturing chemists. We have much sympathy with the desire of pharmacists to avoid the expense and pecuniary risk to which they are subjected by physicians who take up for a short time, and then abandon, the many preparations urged upon them by the agents of these enterprising firms. But the case is by no means so plain as Mr. Emlen supposes. Even the simple laxative pills which he cites as objectionable are, in our opinion, of great utility. He has greater confidence in the average druggist's assistant than we have, or he would not advise physicians in general to prefer extemporaneous preparations to those made in large quantity by firms which have acquired a reputation for integrity and skill in this work. It is not long since the writer of this editorial saw a qualified druggist's assistant measure out three times the ordered quantity of a drug and add it to a mixture nearly complete, which had to be thrown away when the error was detected. This occurrence indicates one of a number of reasons why the preparations of well-known manufacturers are often preferred by physicians to those which they can get made to order in the drug shops. In addition to this, the fact cannot be denied that many medical men are not loath to prescribe a manufactured article which gives them certain results, even though they do not fully understand what are all of its ingredients. To them it is something that they are saved the trouble of thinking out a formula, and they are by no means unwilling to take what they believe is the result of careful and skilful elaboration by others who have made a specialty of it, as a reliable remedy for the conditions for which it is recommended, and to continue to prescribe it as long as it produces the effects they desire.

In this we think they do well, and it rests with the pharmacists to convict them of error if they are wrong.

A more serious objection than that to which we have alluded is raised by Mr. Emlen against certain preparations, which he intimates are actually fraudulent, because they are not made up in accordance with their published formulæ. If this be the case, then they are undoubtedly frauds, and deserve the severest condemnation. But, we may suggest that the pharmacists, who have so great an interest in exposing the false pretensions of those whom they regard as their natural enemies, have an easy way of dealing with cases of this kind. Let a preparation which they suspect be purchased of the manufacturer and analyzed, and then let a suit be instituted against the manufacturer for obtaining money under false pretenses. It would not take many actions of this kind to free the market of preparations which are actually fraudulent. And, until something of this kind is done by those who are alone in the position to do it, pharmacists cannot justly blame physicians for prescribing remedies which accomplish for them what they desire, solely on the ground of unproved allegations.

We wish to say what is right in this matter, and, if we know it, will allow no un-

worthy considerations to influence our expressions of opinion; but we think there are two sides to the question, and we will gladly give space to a temperate discussion of it in our columns. What our readers want is to learn the truth, and we will not hide any of it from them, if pharmacists or manufacturing chemists will place us in a position to speak positively about this important subject.

TREPHINING FOR EPILEPSY.

The operation of trephining for the removal of a source of irritation of the brain which is suspected of being the cause of epileptic seizures is no longer a rare thing in surgical practice, and the indications for performing it are becoming better defined than they once were. At a meeting of the *Société Médicale des Hôpitaux*, February 24, 1888, M. Ferré presented a patient, thirty-six years old, upon whom such an operation had been successfully performed. The man had been wounded on the vertex by a fragment from a bursting shell, and six months later had begun to suffer with attacks of epilepsy occurring about twice every month. There was a small area of hyperæsthesia at one end of the cicatrix, irritation of which brought on epileptic crises. M. Ferré thought that there was no absolute lesion of the cortex, because the convulsions were not limited to any single part, but affected all four of the limbs synchronously. He therefore called upon M. Reclus, a surgeon, to operate upon the patient. M. Reclus performed the operation of trephining, November 29, 1887, and found a slight depression of the internal table of the skull at the posterior part of the cicatrix. Since the operation the patient had had no return of his epileptic attacks.

The issue of this case is encouraging, although it is too soon to say that a cure has been effected. Similar results have been obtained in other cases in which the attacks afterwards recurred. But this fact does not discredit the operation; for it is no small matter to free a patient for a reasonable time from the horrors and dangers of epilepsy, and it is always possible that an actual cure may be effected.

CELEBRATION IN HONOR OF PROFESSOR AGNEW

On the evening of April 6, 1888, a dinner was given to Prof. D. Hayes Agnew, of the University of Pennsylvania, to celebrate the fiftieth anniversary of his graduation in medicine. The banquet was attended by about two hundred and fifty friends and admirers of Dr. Agnew, and was a very brilliant affair. The usual complimentary speeches were made by gentlemen selected to respond to the toasts, and two poetical contributions added variety to the proceedings. In so far the affair differed in nothing from what happens whenever a man of distinction receives a testimonial of this sort. But there was a feature of the occasion which deserves special mention. This was the peculiar atmosphere of affectionate regard for the guest of the evening, which pervaded the magnificent hall in which the dinner was enjoyed, and the feeling that he in whose honor it was given is so sincerely loved, as well as respected, by an unusually large number of his professional brethren. The reason for this may be stated —not so much in praise of its object as for an incentive to others. Skill and perseverence have won for Professor Agnew the admiration of all who know his ability as a surgeon; unblemished integrity has secured for him the respect of all who know his character; but it is his pure unselfishness and uniform kindness to all with whom he comes in contact which has made him the object of a warm affection, which must be dearer to him than any other reward which he has received for his years of faithful labor. Few men have enjoyed such honors as he has enjoyed without exciting the envy of those who never secured them. But for him they come beautified by the assurance that those who may not share them, love him not less, but more, because of them, and see in each new tribute to his attainments and virtues only an occasion for new enjoyment and warmer regard.

Such a life does good, not only by what it accomplishes, but also by what it teaches; and the occasion which calls attention to the principles of such a hero will serve its best purpose if it leads those who admire, to emulate his example.

CARE OF THE PAUPER INSANE.

There is at the present time a Committee of the Senate of the State of New York engaged in taking testimony in regard to the need for and advisability of a proposed law taking from the counties of that State the right and duty of caring for their own pauper insane and handing them over to the State establishments. From the evidence which has been published, and especially from that given by members of the New York Charities' Aid Society, it appears that there can be little doubt that the pauper insane are not so well cared for under the jurisdiction of county authorities, as they are in establishments under the management of the State. This is in accord with experience elsewhere, and is not different from what one would expect who understands human nature, and who knows the conditions under which institutions of this kind are apt to be managed in this country. It is to be regretted that too many such establishments are managed wholly in the interest of politicians, and that the inmates of them are often mere excuses for handling money to those who have charge of them. Happily this condition of affairs is every day more and more giving place to humane and honest methods, which are everywhere sure of the support of intelligent medical men. We call attention to the matter now, because it is possible that among our readers in the State of New York there are those who may very much assist the cause of humanity and of science by lending their aid to those who are, at this very time, trying to rescue the pauper insane of that State from the remorseless grip of the politician. Now is the time to help, and our readers may be able to determine which way the balance of the legislative mind will turn on this serious question.

—Dr. William B. Dewees, of Salina, Kansas, received, on March 19, the gift of a fruit knife which had belonged to his famous ancestor, Prof. Dewees, of the University of Pennsylvania. The knife is made of silver and pearl, and bears the crest and legend of the family of its former owner.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

THE YEAR-BOOK OF TREATMENT FOR 1887. 8vo, pp. 336. Philadelphia: Lea Brothers & Co., 1888. Price, $1.25.

This is one of the most valuable books for its price which is published in this or any country. It contains a summary of the changes in medical practice, the new remedies introduced, and the experience with them and with others which have been longer in use, during the year 1887, made up from the reading and observation of a number of very capable men in England. The classification is according to diseases, so that one who consults these pages can obtain in a few minutes an excellent idea of the present status of therapeutics in regard to any given ailment. The book also has a good index, by means of which the reader may ascertain the different diseases for which any particular drug has been used during the year last past. We can recommend it highly to our readers, feeling sure that it will prove helpful to them in their practice.

ELEVENTH REPORT OF THE STATE BOARD OF HEALTH OF WISCONSIN, 1887. 8vo, pp. 236. Madison, Wisconsin: Democratic Printing Company, State Printers, 1888.

This report contains much interesting reading of the sort common to most publications of like character; but in addition we find in it a number of essays which deserve special notice. Among them, we may mention an exceedingly intelligent review of the subject of bacteria in their relation to natural and pathological processes by Professor E. A. Birge, of the State University, and a timely supplement to it, under the head of "Recent Progress in Preventive Medicine," by Dr. J. L. Kaine, of Milwaukee. In a paper on "The Physical Side of Education," Professor Anderson, Superintendent of Schools in Milwaukee, properly and severely characterizes the tendency to push children too hard in their studies and to overlook the necessity for play—not gymnastics, but actual play. The paper of Dr. B. O. Reynolds, of Lake Geneva, on "Ideal Sanitation," contains a number of truths which would be of great service, if they could be properly impressed upon the minds of the community.

Before leaving this interesting volume, we must commend the effort of the Board to prevent the appointment of unfit persons to the position of local health officers, and express the hope that their suggestions will not lose their effect because they are couched in such temperate language. To our readers, especially those in Wisconsin, we may add that they would do well to get a copy of this report, if possible, and catch from it a spirit of intelligent sympathy with their own State Board of Health, for their own good and for the good of their State.

TRANSACTIONS OF THE CONNECTICUT ECLECTIC MEDICAL ASSOCIATION FOR THE YEARS 1886–7. Vol. I. 8vo, pp. 130. Bridgeport, Conn., 1887.

This volume contains an interesting account of the rise and progress of the organization whose name it bears. Its scientific papers contain much that is creditable to the good sense and power of observation of those who contribute them. If our readers could go over them carefully, we think they

would regret that men who exhibit so much intelligence should persist in contending as vigorously as they do for a name, and fail to see that no school of medicine is so thoroughly eclectic—in the best sense of the word—as that from which they voluntarily exclude themselves. The distinction between those who *call themselves* "eclectics" and those who abjure an exclusive name is one which is to be regretted, because it severs those who ought to be brethren; and it is to be hoped that the time will yet come when those who merely trade upon special designations will be left wholly to themselves, and the honest men who now follow in error their banner will see that they belong with the great army of healers, who have no motto except that which Dr. Oliver Wendell Holmes has so beautifully expressed for them.

TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF WEST VIRGINIA. Twentieth Annual Session, 1887. 8vo, pp. 155.

The West Virginia Medical Society has not yet reached the age of some of its sisters; but it is a vigorous and active member of the family, and can already look down upon a number of juniors. The volume of transactions before us bears the marks of keeping up with the progress of medical science in other parts of the world. It is not easy always to select papers for special mention from such a collection; but we may perhaps designate those on "Hypnotics," by Dr. C. C. Hershman, of the West Virginia Hospital for the Insane, and that of Dr. W. W. Tompkins, of Charleston, on "New Remedies in Surgery," and a short paper on "Non-closure of the Abdomen," by Dr. Wm. Hogue, of Charleston, describing two interesting cases of this defect, and illustrated by a wood-cut. The other contents of this volume are both interesting and instructive, and lead to the regret—so often felt in going through the Transactions of State Medical Societies—that so many of the papers read before these bodies do not get a wider circulation.

Pamphlet Notices.

[Any Reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage stamp.]

THE MEDICINES OF MEDICINE. Reprint of a paper read at the 35th Annual Meeting of the American Pharmaceutical Association. By EMLEN PAINTER, Ph.G., New York, September, 1887. 8 pages.

—Mr. Painter's paper contains a warm plea against the prescription by physicians of special makes of pills and potions, some of which, he claims, are in no way preferable to what any capable pharmacist can compound, and some of which are not at all what they are said by their makers to be.

A VERY VALUABLE LESSON FOR THOSE WHO USE ANÆSTHETICS. By JULIAN J. CHISOLM, M.D., Baltimore. Read before the Baltimore Academy of Medicine, December 6, 1887. 15 pages.

—Dr. Chisolm is one of few surgeons in the United States who habitually uses chloroform as an anæsthetic. He computes his administrations of it at about ten thousand cases. He uses it almost daily, and has never lost a patient from its effects. This remarkable experience adds greater interest to the very interesting story he tells in the pamphlet before us of the narrow escape from death by chloroform narcosis of a little patient on whom he recently performed enucleation of the eyeball. His story serves as an introduction for a strong recommendation of chloroform as an anæsthetic, and a convincing presentation of the way in which it should be administered, as well as of the measures to be adopted in case of threatened death from its effects. This may be expressed in a single sentence: suspension with the head down. We recommend Dr. Chisolm's pamphlet very strongly to the attention of our readers.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—In consequence of the confiscation of three articles by the official Censor, the appearance of the February number of the *Medizinskoïe Obosrenïe*, a leading Russian medical review, has been delayed a month.

—Dr. Benjamin Ward Richardson has written a novel entitled "The Story of a Star; a Romance of the Second Century." The hero is Bar Cohab, the last of the great leaders of the Jewish people in the final struggle for national independence. It is shortly to be published in the orthodox three-volume form by Messrs. Longman & Co.

Correspondence.

Early Accounts of Diphtheria in New England.

EDITOR MED. AND SURG. REPORTER:

Sir:—A medical work printed in London in 1758 came into my possession from the library of an old doctor, entitled *Medical Observations and Inquiries, Vol. I.*, which gives an account of "the first appearance of the throat-distemper at Kingston, an inland town of New England, about the year 1735." This article was an extract of a letter from Cadwallader Colden, Esq., to Dr. Fothergill. The facts were obtained chiefly from correspondence with Dr. Douglass, of Boston.

Kingston being an inland town it was concluded that the disease could not have been imported. It moved slowly westward and did not reach the Hudson river, where Dr. Holden was then stationed, for about two years. And it seemed to attack those towns through which New England people travelled. It continued to travel westward until all the British colonies were attacked. At that time it was considered contagious, although isolated families were affected in the tract of the epidemic. For fourteen years after its

first appearance it continued to break out afresh here and there.

The writer says: "The seeds of this distemper seem to be hatching in the humors of the body, before any particular symptoms of it appear. A corrosive humor bred in their issues, or in other sores, when they had any, and any constitutional ails were sometimes revived." Speaking of the furring on the tonsils, he says: "the tough cream colored sloughs were thrown off. The tonsils appear deeply pitted and corroded, and the sloughs are soon again renewed. Sometimes all the parts near the gullet or throat are much swelled, both inwardly and outwardly, so as to endanger a suffocation, and frequently mortify. Sometimes these swellings imposthumate."

Many of the cases were up and walking about until a very short time before death. And some died before any one suspected any danger. The fatality was great. Some cases were treated with bleeding, and with purgatives. "All sensible evacuations of every kind, after the disease has continued some time, are destructive. The consequences of of them are, a general tendency in the humors of the body to unsurmountable mortifications; so far, that the orifice made by the lancet in bleeding, and the adjacent parts, mortify. So likewise the places where blisters were applied, mortify; and the *ichor*, which issues from them corrodes all the parts on which it distils, and produces mortifications."

Dr. Douglas, of Boston, was given the credit of discovering the first successful method of cure. His treatment consisted in keeping the patient warm in bed, keeping up a free perspiration by warm drinks: sage tea mostly. Serpentaria was used as a diaphoretic. He "found well dulcified mercury of use, especially when joined with camphire." Gargles of a decoction of sumach berries, serpentaria, and alum were used. The compound tincture of aloes mixed with honey was used on the tonsils. Fomentations of bitter herbs, *sal armoniæ*, borax, salt, and vinegar, were used on the throat when swollen.

This article contains many other quaint views on the pathology of this throat disease, as well as on physiology and treatment which will not be quoted here. Already I have drawn sufficiently on the original text to show the prevalence of diphtheria at that early date. Undoubtedly it prevailed before that time, but this writer was unable to bring forward the facts. He recorded it as it appeared at that time.

It also appears that he regarded it as a peculiar form of disease, differing from any that he had seen or read of in England.

Newport, Vt. JOHN M. CURRIER.
March 8, 1888.

Difficult Twin Labor.

EDITOR MED. AND SURG. REPORTER:

Sir:—On Sept. 26, 1887, I was called to see Mrs. Y., about 36 years of age. On my arrival I found her in the first stage of labor. On examination per vaginam I found a breech presentation. The os uteri being well dilated, and seeing nothing unusual in the case, I thought best to let nature do the work. Labor progressed finely until the child was expelled to the shoulders, and one shoulder and arm were expelled. At this stage it seemed to refuse to be moved by the expulsive efforts of the uterus. I then brought down the other arm, and the child was born to the neck. But still it refused to move any further. I introduced my finger up by the side of the neck to try and find out the trouble, when it came in contact with another head, which was presenting lower down than the first, and this was a vertex presentation. Finding out the condition of the case, I was at a loss to decide what would be best to do. However, as the woman was stout, and the expulsive efforts good, I did not have to wait long before the second head came down by the neck of the first child, and the second child was soon born. The next pain brought the head of the one that was born to the neck. Though it had died from pressure on the cord, I tried the prescribed means of resuscitation, but failed. They were carried to full term, weighing seven and one-half pounds each. The mother was not injured in any way and made a good recovery. As this was an unusual case with me, I thought I would report it in a very short manner. Is there any way to diagnosticate such a trouble, and adjust it before the first child's body is born? All that I could do in my case was to place the child in the best position for the other to pass. Would like to hear from the editor and readers of the MED. AND SURG. REPORTER in regard to it.

W. H. BARNES, M.D.
Homewood, Miss., March 23, 1888.

About Advertisements.

EDITOR MED. AND SURG. REPORTER:

Sir:—Your editorial on "Reading Notices," in the MEDICAL AND SURGICAL REPORTER, March 17, p. 347, should receive the hearty approval and commendation of

every reader, and your periodical the substantial support of every just-minded medical man. Advertisements should be confined to the advertising columns. The insertion of "reading notices" and advertisements among the reading columns and pages is detestable and should be deemed good and sufficient reason for casting into the fire any periodical in which this is practiced. True, these notices pay large sums; and it is refreshing to see some secular periodicals rejecting such dishonorable service of Mammon. How humiliating, on the other hand, to note so many religious papers and magazines for greed of lucre, holding up to public gaze disgusting, and even filthy things? Here is one that, under the head (in capitals) "Religious Notices," inserts four lines in the way of religious matter, and then follow a number of short and longer notices of shams and frauds and charlatanisms to draw forth money for those whose "ads" are not allowed in pure secular papers.

D. L. Phares.

Agricultural and Mechanical College, of Mississippi.

March 21, 1888.

Notes and Comments.

Treatment of Epidemic Dysentery.

Dr. J. W. McLaughlin, of Austin, Texas, says: "The following list of medicines comprises those upon which I usually rely to meet the various indications which come up in this form of dysentery: Opium, quinine, turpentine, camphor, naphthaline, mercuric salts, chlorine water, nitrate of silver, sulphurous acid, tannate of bismuth, kino and ergot; concentrated food, meat preparations, milk and brandy. In those grave forms of dysentery characterized by profound toxæmic depression and threatened death from heart failure, I confidently recommend turpentine in large doses. It is an excellent hemostatic, a good antiseptic and a valuable stimulant, well suited from its prompt action to arrest the destructive tendency of this fearful malady, and counteract threatened heart failure." If the pulse is rapid and weak, the patient restless and sleepless, he gives morphia and chloral hydrate to secure rest and sleep; if the pulse is slow and sluggish, the patient inclined to stupor, small doses of atropine for its action upon the terminal ends and ganglia of the vagus. Brandy, digitalis and strychnia are indicated, he says, as cardiac stimulants and conservators, and ergot and kino to control intestinal hemorrhage. Quinine, mineral acids, carbo ligni, resorcin and other antiseptics and astringents, will be found useful in the varying phases of dysentery. He also recommends injections of large quantities of water to which should be added antiseptics and astringents, *e. g.*, boric acid, borax and salicylic acid, tannic acid, nitrate of silver, alum, or chlorine water. In the ordinary run of cases, those in which the system is less profoundly impressed and which pursue a slower pace, naphthalin is recommended and in his hands has given excellent results. The mercuric salts and chlorine water are recommended in the diphtheritic forms, sulphurous acid and tannate of bismuth, in the typhoid forms, and simaruba, columba, nux vomica and cinchona in the convalescent stages. Rest in bed, cleanliness of person and clothing with proper feeding are absolutely essential to the success of any plan of treatment. He objects to the practice of stuffing patients, forcing upon them food when they neither desire it nor can digest it, as he feels sure such practice is harmful to the patient. If the patient desires food and his stomach can digest it, by all means, he says, let him have it, but when the contrary condition is present it is better to withhold food, or select that which is least objectionable to him: sweet milk, peptonised or with lime water; frozen cream if it is grateful, meat juice and meat broths, are to be recommended. The same rules should govern in giving whisky or brandy in dysentery, which are observed in its administration in other diseases.

Food and Food Adulterants.

An article in *Science*, March 23, 1888, calls attention to a recent report of the United States Department of Agriculture on foods and food adulterants, which treats of fermented alcoholic beverages, malt liquors, wine and cider, and represents a vast amount of work by C. A. Crampton, the chemist, and his assistants. The opening sentences of this report are calculated to excite a good deal of thought and reflection. The production of malt liquors in this country is second only in importance as an industry to the production of breadstuffs. Their consumption is steadily on the increase, as is also the amount consumed in proportion to other kinds of alcoholic beverages. In 1840 23,310,843 gallons of malt liquors were consumed in the United States. In 1886 the amount reached 642,967,720 gallons. In 1840 the consumption *per capita* was 1.36 gallons, while in 1886 it was 11.18 gallons. During the same period the consumption

per capita of distilled spirits has decreased from 2.52 to 1.24. It is estimated that the amount expended for beer per annum is $304,852,683, placing the cost to the consumer at 50 cents a gallon. The annual cost to the consumer, of all liquors consumed, is placed at $700,000,000. In speaking of the enormous consumption of beer in the United States, Mr. Crampton, who prepared the report, says that no beverage compares with it, in the amount consumed, except water, and possibly milk; and that but little supervision has been exercised over its manufacture and sale, except the rigorous enforcement by the government of its demands for a share in the profits. The average amount of alcohol, by weight, in American beers is 4.63 per cent. Of thirty-two samples analyzed by the department, salicylic acid was found in seven. These were all bottled beers, one of them being imported. None was found in any of the draught beers. Of the nineteen samples of American bottled beers analyzed, six contained this acid. These six included the product of some of the largest breweries in the country—beers that are used to a very large extent all over the United States. Whether the acid is added in the breweries where the beer is made, or by the local bottlers, could not be determined. The acid is added to prevent fermentation, and, as has been shown by Dr. Bartley, formerly chief chemist to the Brooklyn Board of Health, the amount which beers contain is sufficient to be injurious to health. Of seventy samples of wine examined by Mr. Crampton, including champagne, burgundy, claret, sherry, sauterne, and other wines in common use, eighteen contained salicylic acid, and thirteen sulphurous acid, which had been added as such or in the form of a sulphite. One sample in forty contained one aniline dye-stuff, probably fuchsine; this was a California claret. In the analyses which were made of cider, some were found to contain as much as 8.09 per cent of alcohol by weight, the average being 5.17 per cent. These were all well-fermented ciders, and all bottled but one. In the 'sweet' or incompletely fermented ciders, the percentage of alcohol averaged 1.40, the lowest being 0.20, and the highest 3.46. No salicylic acid was detected in any of the ciders examined, and but one was adulterated. This was a bottled "sparkling cider," handsomely put up in neatly capped bottles, and of a clear, bright color. In it were found both bicarbonate of soda and a sulphite. This report is in its entirety a most valuable one, replete with information which is interesting to the general reader, as well as instructive to the scientist.

The Female Doctors.

Several years ago three Russian female doctors established a hospital and dispensary for Mohammedan women at Tashkend, the capitol of the now Russian province of Sir Darya. The idea was a happy one, and it has been attended with the best results, for an institution of the kind filled a long-felt want. Patients attended daily, who otherwise would have had to go without medical assistance, as doctors are not admitted in Mohammedan homes. Last year the three lady doctors gave no less than 15,000 consultations at their establishment.

A Drug Clerk's Fatal Mistake.

The *National Druggist*, Feb. 15, 1888, states that a prescription clerk in St. Louis made a mistake in the substitution of compound syrup of ipecacuanha (Dover's syrup, or syrup of Dover's powders) for syrup of licorice. The child for whom the prescription was ordered, died after taking a few doses of the medicine, and the clerk was immediately arrested and locked up. This is only one more instance emphasizing the necessity of including dover's powder and the syrup thereof among the poisons, and keeping them in the poison case.

Formula for Syrup of Yerba Santa.

E. Y. Johnson, in a communication to the *Druggist's Circular*, April, 1888, says that the following syrup will effectually disguise the taste of forty or more grains of sulphate of quinine to the fluid ounce. He says he has questioned several physicians who have used a great deal of it, and all say it gives perfect satisfaction. The following is the formula:

Fl. ext. yerba santa	1 fl. oz.
Carb. magnesia	6 drs.
Refined sugar	4 fl. oz.
Water	4 oz.
Oil of pimenta	10 drops.
Oil of cloves,	
Oil of cinnamon, of each	6 drops.

Rub the magnesia and sugar together until thoroughly mixed, then drop in the oils and the fluid extract of yerba santa, and rub until nearly dry. To this add the water, mixing well, and lastly, add a mixture of glycerin 4 ozs., water 5 ozs., rub well, pour on a filter and add water to make the filtrate measure 15 fl. ozs. In this dissolve by agitation refined sugar 14 ozs. (av.), and add to the

whole mixture citrate of potassium 75 grs. previously dissolved in a little water and let stand two hours. Filter through a wetted filter, returning until it passes clear. The above, he says, gives a perfectly clear, brilliant syrup which will not cloud by standing.

Horrible Murder by a Monomaniac.

A very singular occurrence, says the *British Med. Journal*, February 11, 1888, has recently taken place at Gortley, a village not far distant from the famous Gap of Dunloe. On Saturday, February 4, six members of one family, in a fit of madness, murdered an idiotic boy, 13 years old, and threw his body into the yard adjoining the house. The perpetrators of the deed are now inmates of Killarney Lunatic Asylum, but the mother of the lad confessed to have had some hallucination that so long as he lived the family would be subject to evil influences. On this account she acknowledged having killed her son with a hatchet.

Toothache Pellets.

The *Chemist and Druggist*, March 17, 1888, suggests the following:

Cocaine hydrochlorate	grs. 16
Powdered opium	grs. 64
Menthol	grs. 16
Powdered althæa	grs. 48
Mucilage of acacia	grs. 9

Make into ½-grain pills and keep in well-stoppered vials. For use, one of these is to be inserted into the hollow tooth.

State Medical Society of Arkansas.

The next meeting of the State Medical Society of Arkansas will be held at Fort Smith, April 25, 26 and 27, 1888. It promises to be one of the most largely attended meetings since the Society was organized. A large number of interesting papers have been promised, most of them of a highly practical character.

The sessions of the Society will be held in the hall of the Young Men's Christian Association, beginning on Wednesday morning. Reduced rates of fare will be granted to those members of the Society who purchase not more than five days before April 25, full fare tickets to Fort Smith, taking a certificate from the ticket agent, which will be endorsed by the Secretary of the Society, and secure return tickets at one cent a mile. Return tickets must be purchased on or before April 28.

The Secretary of the Society is Dr. L. P. Gibson.

NEWS.

—Sir Andrew Clark has been elected President of the Royal College of Physicians of England, succeeding Sir William Jenner.

—Dr. John M. Browne has been appointed by President Cleveland Surgeon-General, to succeed Dr. F. M. Gunnell, whose term expired March 26.

—Professor Hattie Allen, who has just assumed an important chair in the Medical Department of the University of Michigan, is said to be only thirty years old, and is a Vassar alumna.

—The California State Medical Society will hold its annual meeting, April 18, in San Francisco. Dr. C. G. Kenyon, 664 Mission St., San Francisco, is chairman of the Committee of Arrangements.

—It has been proposed that a statue or a monument be erected to perpetuate the memory of the late Henry Bergh, the world-famous friend of the dumb animals, and consequently the friend also of humanity.

—S. Moriyasu, from a study of a large number of Japanese girls with reference to the age at which menstruation began, concludes that the first appearance is on an average between the ages of fifteen and sixteen years.

—The *Kansas City Medical Index*, March, 1888, says that one of the brightest and most promising young physicians of that city, has been forced to give up his practice—in fact, has become a perfect physical wreck—from the use of cocaine.

—Dr. Nicholas Senn has been appointed Professor of the Principles of Surgery and Surgical Pathology in the Rush Medical College, Chicago; and Dr. Frank T. Andrews Professor of Practical Medicine in the Chicago Medical College.

—The death of Dr. Leopold von Holst, who was for a long time one of the editors of the *St. Petersburger med. Wochenschrift*, is announced. He had been a sufferer for many years from chronic bronchitis and emphysema, but his death was occasioned by pyæmia. He died March 6.

—The degree of Doctor of Medicine was conferred upon 188 graduates of the Jefferson Medical College at the sixty-third annual commencement, April 4. Professor J. W. Holland, Dean of the Faculty, awarded the prizes, and Professor Roberts Bartholow delivered the valedictory address to the graduates.

HUMOR.

"EVERYTHING I HEAR goes in one ear and out of the other," said a dude to Charley St. Clair yesterday. "Why shouldn't it?" said Mr. St. Clair, "for there's nothing to stop it."—*Boston Beacon.*

"FATHER," SAID THE EDITOR'S LITTLE BOY, "is the new Emperor of Germany an editor? I see when he speaks of himself he says 'we.'" "No, my son. That is a word the emperors have stolen from the editors without proper credit."—*Peoria Transcript.*

EXCITED WIFE—O John! John! Quick! Stop fumbling behind that bureau and run for a doctor. Half-dressed husband—What's the matter with you, anyhow? "Baby has swallowed your collar-button." "How on earth do you expect me to get ready to go for a doctor without that collar-button?"—*Omaha World.*

"YOU OUGHT TO BE ASHAMED OF YOURSELF, a great big man like you to be a beggar and a tramp! You oughtn't to be afraid of work." "I know it, mum, but I can't help it. You see my nurse frightened me once in a dark room when I was a baby, and I have been timid ever since."—*N. Y. Mail and Express.*

OBITUARIES.

BENJAMIN F. DAWSON, M.D.

Dr. Dawson died in New York at the age of 43 years. He served as Acting Assistant Surgeon in the United States Army during the last year of the rebellion. After graduation at the College of Physicians and Surgeons in 1886 he paid special attention to obstetrics and the diseases of women and children. In 1868 he founded and until 1874 edited the *American Journal of Obstetrics*, and to that and other similar publications was a constant contributor. In 1876 he invented and published an account of a new galvanic battery for galvano-caustery surgery, which attracted much attention. He was a member of numerous societies, medical and scientific.

JOSEPH A. PAXSON, M.D.

Dr. Joseph A. Paxson died at his residence in Philadelphia, April 5, after a short illness. Dr. Paxson was born in Bucks county, in 1842. He came to this city in 1863 and became a teacher in the Friends' School at Fifteenth and Race streets. He was graduated from the Medical Department of the University of Pennsylvania in 1869. After practicing medicine in Buckingham, he came to Philadelphia in 1875. He held at different times several positions of trust, and took considerable interest in political matters. His wife and two children survive him.

WILLIAM C. SPENCER, M.D.

Dr. William C. Spencer, died of pneumonia at Fort Trumbull, Conn., March 22, after an illness lasting two days. He was appointed Assistant Surgeon in 1861, promoted to Captain and Assistant Surgeon in 1866, and to Major and Surgeon in July of the same year. He was breveted Lieutenant-Colonel March 13, 1865, for faithful and meritorious service during the war. He was fifty years of age.

WILLIAM B. SMALL, M.D.

William B. Small died in Philadelphia, March 31, at the age of about 75 years. He was born in Philadelphia, and was graduated from the University of Pennsylvania in 1833. From that period until within a short time of his death he was in active practice. In his earlier years he gained a reputation for his services in various epidemics of small-pox and yellow fever, and was physician to one of the pest houses, at that time located at Bush Hill. He was at one time a member of the City Gas Trust and was Chairman of the Committee on Distribution.

THOMAS F. TEBBS, M.D.

Dr. Thomas F. Tebbs, of Prince William county, Va., died in Haymarket, Va., January 27, 1888, after a short illness. He was graduated from the University of Pennsylvania in 1849.

Official list of changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from April 1, 1888, to April 7, 1888:

Col. Jedediah H. Baxter, Chief Medical Purveyor, Maj. Chas. R. Greenleaf, Surgeon, detailed as members of an Army Retiring Board, appointed to meet at Washington, D. C., on Wednesday April 4, 1888. S. O. 75, A. G. O., April 2, 1888.

Maj. Chas. H. Alden, Surgeon, will repair to Washington, D. C., on public business, and on the completion thereof will return to his station (West Point, N. Y.) S. O. 75, A. G. O., April 2, 1888.

Capt. Victor Biart, Asst. Surgeon, having been found incapacitated for active service by an Army Retiring Board, sick leave of absence is still further extended until further orders on account of disability. S. O. 77, A. G. O., April 4, 1888.

Capt. Edwin F. Gardner, Asst. Surgeon, leave of absence extended fourteen days. S. O. 77, A. G. O., April 4, 1888.

Official list of changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the four weeks ended April 7, 1888:

S. T. Armstrong, Passed Assistant Surgeon, granted leave of absence for fourteen days. March 21, 1888.

W. D. Bratton, Passed Assistant Surgeon, promoted and appointed Passed Assistant Surgeon, from April 6, 1888, April 2, 1888.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superintendent and his assistants. **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

OPERATION UPON A LACERATION OF THE CERVIX AND PERINEUM: PERITONITIS, ABDOMINAL SECTION, DEATH.

BY HOWARD A. KELLY, M.D.,
PHILADELPHIA.

It is a saying as true as it is trite, that a careful study and a proper appreciation of the causes of our failures, frequently teach us more than many successes. And to this end, with a desire to extract as much good as possible from a very sad case, which has recently occurred in my surgical practice, I present the following report:

Mrs. B. came to me from a distance, sent by her family practitioner, a man of high skill and reputation, living in the northern part of the State. I found upon examination, that she had a very unusual form of laceration of the cervix, extending obliquely from the left, anteriorly, to the right, posteriorly, completely dividing the cervix into the vault of the vagina, leaving two puffy infiltrated lips. From its anterior left extremity, the tear had extended far into the vault and leaving as its sequel a well-defined, broad, sharp-edged band of scar tissue. The vaginal outlet was slightly torn, and greatly relaxed. A careful bimanual examination showed that the pelvic connective tissue also carried the scars of old inflammation, but there were at present no foci of any active, or sub-acute inflammation, nor were there any cystic deposits or pus pockets discoverable within the pelvis. The injury was one of which I have seen many examples, resulting apparently, in the light also of the well detailed history, given me by her physician, from a very difficult forceps labor, occasioning great damage to the maternal soft parts, and followed by a severe attack of puerperal fever, confining her several months in bed. She was etherized for operation on the 9th of March. Both cervix and perineum were repaired at the same sitting, lasting about forty minutes; and I followed the same steps satisfactorily employed in several hundreds of cases previously. She took the ether very badly, resisting violently when inhaling it, and retching for a long time as she was coming out of its influence. In brief the operation was conducted as follows: The cervix was well exposed by Simon specula, and held by a tenaculum, exercising very little traction, on account of the condition of the vaginal vault and connective tissue above mentioned. The lips of the tear were quickly denuded with scissors, and brought together by three sutures of silk-worm-gut on one side, and two on the other, which were held by clamped shot. No sponges were used throughout. Cleanliness and comfort were insured by continuous irrigation, pouring a steady stream of carbolized water on the field of operation. The relaxed vaginal outlet was quickly repaired by means of the Emmet operation, and closed with shotted silk-worm-gut sutures. For thirty-six hours the patient's condition was comfortable, and there was nothing to excite especial attention, until on the third day I noticed a quickening of the pulse, for which she was given tincture of digitalis, which was stopped on the day following on account of vomiting. Her pulse on the fourth day was 124, and she was vomiting frequently, and complaining of pain across the lower part of the abdomen. Throughout this day and the day following, in spite of the most careful attention, close watching and judicious medication and feeding, the pulse continued from 120 to 130, and the temperature ranged from 100° to 102°. The next day

at midnight the matron of my hospital called me, with the report that the pulse had gone up to 140. I ordered her to prepare at once for an abdominal section, with thorough irrigation of the peritoneum. My associate, Dr. Robb, who was dressing to go with me, asked me if it would be well first to take out the stitches in the vagina and cervix? I replied that I was certain that some as yet mysterious cause had given rise to an attack of *peritonitis* instead of cellulitis, and I felt equally confident that the field of operation was not directly to blame. Several possibilities lay before me—either in some unaccountable way, unprecedented in my experience, the field of operation had become infected, and transmitted the poison to the peritoneum; or else some lingering trace of the old pelvic inflammation, in the shape of a small pus cyst had been ruptured by manipulation during the operation or vomiting, and the peritoneum had thus directly been infected. My confidence in the conditions which surrounded the field of operation was such that I unhesitatingly acted at once upon the latter supposition, which was supported by a careful digital examination per vaginam, showing that there was no deposit in either broad ligament. Under the influence of chloroform, with the assistance of Dr. Hunter Robb, I quickly opened the peritoneum, and was at once rewarded by finding about two ounces of grumous pus lying free in the pelvis among the intestines. I washed the cavity out well, and closed the incision down to a drainage-tube, in the lower angle, resting in the pelvis. A curious fact attracted my close attention when making the incision; after cutting through the skin and fasciæ, I opened a small duct-like structure, plicate, and looking like bladder tissue. I feared for a moment that this was an unobliterated urachus. But as no discharge came from it, I continued opening the peritoneum. She informed me on the following day, that she had for some years had an intermittent purulent discharge from the navel, which in the interim appeared clean and healthy. This discharge ceased from this time, and I could discover no trace of it subsequently. The first object of my care upon opening the peritoneum, and finding the puriform grumous accumulation, was to discover the condition of the pelvic organs. I slipped my fingers behind the uterus, and found that ovaries, tubes, broad ligaments, uterus and cervix were normal. No adhesions and no cysts were to be found. After this operation the pulse quickly dropped twenty beats, the sickness of the stomach was relieved, and pain disappeared; the temperature fell a degree and a half, and the pulse continued dropping, until it reached 108 in thirty-six hours, with constantly improving general condition. It then began to climb again, and in forty-eight hours had once more reached 138, went to 150 and 160, with complaints of oppression, and pain in the right chest. In order to make certain that no lingering focus or sepsis remained in the abdomen, I once more irrigated the peritoneum with warm water, but without discovering any pus. The chances of recovery after this second rise in pulse, accompanied by rise in temperature, were very small; and the association of these factors with the complaints of pain in the chest, made the whole aspect of the case peculiarly ominous. Previously to this I had removed the stitches from the outlet, and found that it had healed perfectly throughout, affording one of the best closures I have ever made. The peritonitis after removal of the pus remained dry, the intestines had lost their lustre, and here and there were a few flakes of white lymp, like small shreds of curdled milk.

I have studied enough cases of peritonitis, watched with an anxious observance of the minutest symptoms, to speak with assurance, when I say that there did not remain sufficient cause in the peritoneum after cleansing to occasion death under ordinary conditions of vital force. The conviction was therefore unavoidable that the immediate cause of death, distress in the chest, and the rapid pulse, were due to clot forming in the great vessels. I remained by the bed-side myself all the last night, administering stimulants by mouth and hypodermically every fifteen minutes, until a late hour on the day following, when, with many fluctuations and short seasons of illusory apparent improvement, she died late in the afternoon, nine days after the first operation.

The bare outline of the case as above given stands thus: First, an operation upon the perineum and cervix, accompanied by a violent commotion of the abdominal viscera, due to the anæsthetic. Next, peritonitis distinctly recognized as such on the fourth day. Third, abdominal section for peritonitis, with thorough cleansing of the peritoneum and drainage. During the section a tubular canal was discovered, probably communicating with the umbilicus, a remnant of a fœtal duct. The secretion from the navel probably came through this, and was probably under the straining efforts forced into the peritoneal sac. After this operation and the drainage, prompt marked improvement, suddenly interrupted by the forma-

tion of heart clot; terminating in death, which was due therefore to a rare accidental cause undiscoverable prior to an operation.

MERCURIC CHLORIDE IN CHRONIC PARENCHYMATOUS NEPHRITIS.

BY THOMAS A. POPE,
CAMERON, TEXAS.

Case I.—F. H., aged 17, applied to me for treatment in April, 1882. Had been under treatment for several months before I saw him. As well as I could learn, the treatment had been anti-malarial. The eyelids and feet were slightly œdematous; the tongue coated; the bowels irregular, generally constipated, but occasionally there was diarrhœa; appetite capricious. Sometimes the patient vomited food; nutrition bad, as evidenced by flabby muscles and loss of weight; constant headache in occipital region; more or less pain in back, and a constant feeling of lassitude, and a very little exertion was very fatiguing; passage of urine caused a burning pain along the urethra.

On examination, I found the specific gravity of the urine to be 1035, and it contained about one-fifth its bulk of albumin. The quantity passed was about normal, but perhaps slightly reduced. As the patient had been taking quinine for months I gave him a mixture containing iron, arsenic and nux vomica, and also one containing bitartrate of potash and fluid extract of digitalis. This treatment was continued for a month without any improvement in the general symptoms or diminution in the quantity of albumin. I then prescribed:—

℞ Hydrarg. bichlorid.....gr. ij
Alcoholis q. s. to dissolve.
Ammon. chlorid.....gr. x
Aquæ menth. piperit.
Syr. simplic.....āā. f℥ ij
M. S.—A teaspoonful after each meal.

Also:—

℞ Potass. acetat..... ℥ j
Spt. ætheris nitrosi.....f℥ j
Aquæ.....f℥ j
M. S.—Teaspoonful once or twice every day.

I prescribed the mercuric chloride partly because I did not know what else to do, but principally because I knew it to be a tonic, an alterative, and useful in inflammations elsewhere, and that it would promote absorption of morbid growths when all other remedies were useless. I gave the alkaline mixture because I wanted the volume of urine to be large, and because I supposed that the pain caused by the passage of urine was due to its acidity, and wished to render it alkaline. Under this treatment there was, at the end of one month, a decided improvement in all the symptoms, and the amount of albumin was decidedly lessened. The alkaline mixture was discontinued, and from that time the patient took nothing but the bichloride solution and sulphate of magnesia, if needed, and some quinine on one or two occasions. At the end of eight months he was in the enjoyment of perfect health, and not a trace of albumin could be detected in the urine. To-day he is still in perfect health.

Case II.—In January, 1883, Mrs. B., aged 33 years, had an attack of acute parenchymatous nephritis. She was treated as usually directed for acute attacks of Bright's disease, and in about two weeks was apparently completely recovered. About three months afterwards I was called to see the same patient and found her suffering from chronic parenchymatous nephritis. I prescribed a bichloride solution, as in Case I, and gave nothing else, except a preparation of pepsin for digestive trouble and sulphate of magnesia when indicated. In three months the albumin disappeared and has never returned, and she has since enjoyed excellent health. Mrs. B. was not pregnant during the time she suffered from albuminuria, but has since given birth to two children.

Case III.—F. W., November, 1884, had been complaining for several months, and had taken a quantity of patent medicine. His symptoms led me to conclude there was some kidney trouble, and on examination I found albumin. This patient was put on the same treatment as the previous cases. For three months the albumin was constant; but at the end of that time it was lessened in quantity. The patient lived nearly twenty miles away, and had his prescriptions filled at home. At the end of two months he was able to work, and I did not see him for three months. He was then enjoying good health with no trace of albumin in his urine. I have not seen him since, but have heard he still enjoys good health.

Case IV.—W. N., aged 42, had felt badly for a long time, but did not apply for treatment until trouble with vision interfered with his profession of teaching. His eyesight was so bad that he could not read small print even with glasses, and small dark objects were constantly floating before his eyes. This patient was under treatment for eight months, and under my observation for a year longer. Under the use of bichloride of mer-

cury the albumin disappeared in five months, and perfect vision returned two months earlier. Since the disappearance of the albumin, he has been in perfect health.

Case V.—Mrs. F., was confined a year ago; I did not see her previous to her confinement. A few days after her confinement I examined her urine and found it loaded with albumin. From a history of the case I was satisfied that she had been suffering with albuminuria for at least two years. I put this patient on the bichloride, and she did not cease to take it until she was convalescent. About four weeks after her labor, she became partially paralyzed on the left side of the body and the right side of the face. In addition to the mercuric chloride she took strychnia, and opiates when indicated. Within five months she was convalescent, and has since been in better health than she had enjoyed for two years previous to her confinement.

Out of fifteen cases treated long enough in the past to be certain of results, I have selected five as illustrative of the whole. All of the fifteen cases recovered, and I know that eleven of the patients are to-day in good health, and the others were when last heard from. There were of course many symptoms present in these cases that are not given, simply because minute detail was not deemed to be necessary to illustrate the treatment, which was, as may be seen, very simple.

In all these fifteen cases the albumin was considerable and persistent for months. Albumin in the urine is not *per se* sufficient evidence to diagnosticate chronic Bright's disease, as its temporary appearance may be caused by violent exercise when the tissue waste is not converted into urea, by vasomotor disturbance in nervous persons, by congestion of the kidney, by ingestion of egg albumen, by various drugs, pregnancy, heart disease, and acute Bright's disease, and perhaps from other causes. But if we exclude these, and the albumin is persistent, then we may conclude we have chronic Bright's disease even if there be no symptoms pointing directly to kidney trouble.

But it is very rarely that we find persistent albuminuria without other symptoms to confirm the diagnosis. I am sorry that the lack of a microscope has prevented my making a microscopical examination of the urine in all these cases, as I then might have been able to make some definite observations on the pathological condition of the kidney in the patients treated.

As to the cause of chronic parenchymatous nephritis, while it has been ascribed to malaria, syphilis, alcohol, etc., there is no positive proof that these are direct causes. It is true that a patient with a weakened constitution from whatever cause would be more liable to acquire this disease than a man of sound constitution and in robust health.

Drs. Da Costa and Longstreth, in a paper which I have not had the pleasure of reading, state that in chronic Bright's disease there is found fatty degeneration of the ganglionic centers, and they think that the fatty degeneration of the renal ganglion is a cause of chronic Bright's disease. If this be true, it is a fact of great importance when we come to treat the disease.

The large white kidney is the kidney of chronic parenchymatous nephritis, and I think it probable that this kidney always precedes the granular or cirrhotic. Notwithstanding the fact that Bartholow and others state that interstitial nephritis is generally a primary disease, and seldom follows chronic parenchymatous nephritis, there is so far as I can find absolutely no evidence to confirm the statement. If we make it a practice to examine the urine of all office patients, we often find albumin when there is nothing in the symptoms of the patient that leads us to suspect it, and there are, no doubt, hundreds of persons suffering from chronic Bright's disease who appear to be in perfect health and complain of no trouble whatever. And if at the autopsy we find the granular kidney, what proof can there be that it was the primary, and not the secondary affection? There may have been no symptoms at all during the parenchymatous stage, and it may have been only after the interstitial tissue became affected and the kidney contracted that the renal trouble was developed.

Whether chronic nephritis follows the acute, or is always primary, is hard to determine. In one of my cases the chronic followed the acute form, but the patient may have been suffering from the chronic form before the acute was developed. If the patient was under observation previous to the acute attack, and no kidney trouble was present, it would be clear that the chronic followed the acute. But whether always primary or not the condition of blood and renal organs is the same when the chronic form appears.

Belfield and others state that nearly all cases of acute Bright's disease are of blood origin, and it seems reasonable to conclude that the chronic form originates in some blood dyscrasia or nerve trouble, and if by some remedy acting on the blood and nutri-

tion we can cure the disease it will be strong proof that such is the case.

The condition of the kidney cannot always be determined by the clinical symptoms. While general anasarca and a large amount of albumin and diminished urine is generally supposed to indicate large white kidney, and polyuria, little albumin and no dropsy, the granular kidney, the latter condition may often be found in the large white kidney.

It is of course the renal epithelium that suffers most in the large white kidney. The glomeruli show evidence of fatty degeneration, as well as the epithelium of the convoluted tubes. The lumen of the tubes may be closed by the coalescence of the cells. If there is no change for the better the interstitial tissue becomes inflamed and the granular kidney appears.

The solids of the urine escape through the convoluted tubes and Henle's loops, while the watery portion escapes from the blood in the glomeruli. I note this fact, because it has a direct bearing on the treatment. Anything which increases the pressure in the glomeruli will increase the flow of urine, as well as anything which increases the diffusibility of the blood. The urine is an index to the metamorphosis of the albuminous constituents of the tissues. This tissue waste is converted into urea and so eliminated. If not so converted it may appear in the urine as albumin.

Now let us look for a moment into the action of the mercuric chloride on the human economy.

Our knowledge of the action of this drug in the various troubles for which it is used is purely empirical, but the vast array of clinical facts has proved its value beyond any doubt. In some way it is certainly antagonistic to inflammation. We use it in iritis, hepatitis, and in all cases where there is a fibrinous exudate. Sir Henry Holland states that he has seen it promote the absorption of morbid growths, and change the character of morbid-action in cases in which all other remedies had proved powerless. After protracted use of any preparation of mercury in large doses the blood becomes watery, and its solid constituents are diminished, and a large percentage is eliminated with the fæces; but in small doses it is a tonic and alterative, and most of it is eliminated by the kidneys. In small doses it aids nutrition in a remarkable degree, increases the glandular secretions, and increases the number of red blood corpuscles. Even small doses of the bichloride lower the arterial pressure, and of all preparations of mercury it is the least liable to salivate. I have used it in doses of 1-12 to 1-10 of grain three times a day for a year, and saw no signs of ptyalism. Corrosive sublimate renders the urine alkaline, increases the amount of urine and promotes the action of diuretics, probably by increasing the diffusibility of the blood.

Mercury acts by preference on the skin and mucous membranes; it is the most powerful antiseptic known. In mumps it will relieve the swelling and pain. Dr. Keyes states that even in healthy individuals the bichloride increases the number of red blood corpuscles, and those who give it in syphilis know that while taking it the weight of the patient increases, the nutrition is improved, and anæmia disappears. It promotes absorption of effused products in any part of the human economy, and is indispensable in some form in glandular enlargements, and is a valuable agent in fatty degeneration.

Those who have used this agent in the treatment of chronic Bright's disease because the patient was syphilitic, speak in high terms of its efficacy. Have they any reason to suppose that the disease is more easily cured when complicated with syphilis than when it is alone?

This article is too long already, and I shall leave the facts as I have collated them from various authorities to speak for themselves. In a future article I shall give my further experience, and in so far as clinical researches will enable me to do so, the various reasons for giving the bichloride in chronic parenchymatous nephritis; and in the meantime I shall be glad to hear from those who would object to the treatment and their reasons therefor.

CASE OF MALIGNANT DISEASE OF THE INGUINAL GLANDS; OCCURRING IN THE PRACTICE OF

M. L. HERR, M. D.,
LANCASTER, PA.

(Reported by Theodore Diller, M.D.)

Through the courtesy of Dr. M. L. Herr, I frequently saw the case here described, and I report it, by his kind permission, principally because of the interest attached to the diagnosis.

Jno. M., aged 22, tobacco packer, always enjoyed good health up to May, 1887, when he says he ruptured himself while lifting the end of a heavy wagon; he said he could distinctly feel something "give way," and that he could feel a tumor in his right groin which did not disappear when he laid down at night, except on *one* or *two* occasions. A

few days after the rupture appeared he procured a truss, which he wore about two months, although he complained that it never fit him properly, and caused him more or less pain. This induced him to get a new truss, which he did at this time; but he did not receive the comfort from the new instrument which he had anticipated. On the contrary, the pain steadily increased until the latter part of November, when Dr. Herr was called to see him. He had taken to his bed, and was, when first seen, lying on his right side with the corresponding thigh flexed upon the abdomen. Examination of the right inguinal region revealed the presence of a hard swelling about the size of an egg, just over the region of the external ring. The mass was firmly adherent to the tissues beneath, but the skin over it was freely movable. Handling the tumor caused the patient considerable pain. On being questioned closely he admitted that the enlargement was at this time distinctly greater than when the trouble began. He was kept in bed, and clay poultices were applied to the swelling, and opium was given internally. Diet was restricted. These simple means proved efficacious in relieving the pain and tendency to vomiting. The diet was then cautiously increased, and a tonic was given until January 10. During this time (six weeks) the tumor had distinctly increased in size, and the patient complained more of pain, while the diminution of body weight was quite noticeable. Moreover, the tumor had become more firm to the feel, and a peculiar dusky appearance of the skin over the growth, together with the above facts, made the diagnosis of malignant disease seem probable.

After consultation with Drs. S. T. and M. L. Davis, and C. E. Netscher, it was decided to remove the mass. The operation was performed by Dr. Herr, January 10. An incision was made one and one-quarter inches above and parallel to Poupart's ligament. Four tumors, ranging in size from a marble to a hen's egg were removed. The ring appeared normal, and no evidence of an entero-epiplocele or epiplocele could be found. The wound was packed with lint saturated with carbolized oil, which was renewed frequently —the wound always being cleansed thoroughly at each dressing with a solution of bichloride (1–2000). Notwithstanding these antiseptic precautions, the cut surface rapidly assumed a grayish appearance, and in a few days the bottom of the wound began to break down and form pus. It was, in fact, impossible to keep the room free from the unpleasant odor which constantly emanated from the part. On January 18, a small painful enlargement was noticed in the other groin; but the condition of the patient at that time was such that further surgical interference was out of the question.

As soon as the effects of the anæsthetic which had been used at the operation had passed away the patient began to vomit, and this troublesome symptom persisted until the day of his death—two weeks later. Cocaine, oxalate of cerium and carbonated water were given with the hope of allaying the gastric irritation, but all proved ineffective. The bowels were moved only with the aid of a purgative.

An autopsy was held twenty-six hours after death by Dr. Herr and myself. The wound made at the operation presented a uniform gray granular appearance. The internal abdominal ring on the right side, as well as the left, was altogether impervious, and they both resisted firm pressure of the finger. The intestines in both iliac regions presented a healthy appearance. In the *mesentery* was found a tumor the size of a child's fist—irregular in outline and light gray in color. Immediately surrounding this tumor in all directions, in radii of from one to one and one-quarter inches, was a mass of hard, gray indurated material. Along the entire length of the abdominal aorta, in some places entirely covering it, was a strip of soft gray structure, looking not unlike a racemose gland in appearance. There were a few lympathic glands along the aorta, which were enlarged, but had not fused themselves, as yet, so to speak, into this long, fleshy strip. The pancreas was enlarged, and attached to its superior border were two or three friable growths resembling the mass along the aorta. The *stomach* contained a small quantity of light-brown fluid. Mucous membrane was light gray in color. Along the greater curvature were three or four spots of fine ecchymosis. Near the middle of the greater curvature, about three-quarters of an inch apart, were two round ulcers. They were each about one-quarter of an inch in diameter, and both presented a "punched out" appearance, with clean cut edges, around which were small rings of congested mucous membrane. About one and one-quarter inches to the left of the nearest of these two ulcers was a small eroded spot—a little bigger than a pin's head—apparently the beginning of a third ulcer.

The *transverse colon*, instead of going directly across the abdomen just below the liver, assumed a V-shaped appearance. The

ascending colon reached the usual height and then turned upon itself and descended in a vertical line almost to the fundus of the bladder; it then ascended vertically to the left hypochondriac region to the point at which the colon receives the name descending. From here, in the remainder of its course, it was normal. The dependent portion contained a large amount of fæcal matter.

My friend Dr. A. J. Smith, to whom I referred the tumor taken from the groin, regards it as carcinomatous, but I myself rather incline to the opinion that it is a sarcoma—perhaps a lympho-sarcoma as suggested by Dr. H. F. Formad.

The case seemed to me to give rise to several interesting points in diagnosis, viz.: Did the man originally have a hernia as he stated, and was the enlargement in his groin occasioned by a simple adenitis and cellulitis, caused by an ill-fitting truss?

True, manipulation of the mass when the patient was first seen disclosed the fact that no hernia existed at that time, and that no amount of coughing would produce one. What then caused the somewhat painful swelling? Apparently it was not a bubo. The most likely diagnosis was that it was a severe adenitis caused by the irritation of a truss. But from this time, about November 25, until January 10, the general condition of the patient had deteriorated so markedly and the growth had increased so much in size that diagnosis of malignancy, at the latter date appeared most likely to be correct. I now think that the most plausible supposition is that the growth began *primarily* in the omentum, that the patient on discovering one day that there was a small movable painful lump in the groin, thought it was a "rupture." By pressing the enlarged gland into the external ring it would seem to "go back." Whether or not the wearing of a truss hastened the growth of the secondary tumor in the groin, it would be difficult to say, but the tumors in the abdominal cavity with the constitutional disturbance which they produced seem to me to be quite sufficient cause for the early fatal termination. The gastric ulcers can easily be accounted for by the fact that the stomach was, like all the other organs, in a very atonic condition, which as we know renders it prone to this affection. The general constitutional condition was also doubtless the cause of the curious anomaly of the colon which was noted.

—The second Congress of German Gynecologists will be held at Halle, May 24-26, 1888.

TWO CASES OF COLIC IN ADULTS, PRODUCED BY INTESTINAL WORMS.

STANLY M. WARD, M.D.,
ELLENVILLE, N. Y.

As is well-known, any irritating body within the intestinal canal is apt to produce that peculiar and excruciating pain called indifferently colic, ileus and enteralgia; that sometimes this complaint is due to worms is hinted at—sometimes broadly suggested by certain writers, but I am led to believe parasites are more frequently the cause of it than is generally supposed. I have also noticed in the course of a somewhat extensive reading, that very few writers, under the head of parasites, treat at length of colic as one of the most striking symptoms presented by those thus afflicted. Indeed, "worms" seem to have been relegated to the charge of "grandmothers," or else is treated from the standpoint of the naturalist.

I was called late one Saturday night, not many months ago, to see Mrs. O., the mother of a large family, who was somewhat neurotic, but withal a strong, hard-working woman. She complained only of intense pain in the stomach and abdomen—a pain which had came on suddenly about three hours before my visit. There was neither vomiting nor diarrhœa, no increase in temperature; pressure over the abdomen had no effect on the pain. There was no swelling or tumefaction; tongue clean, pulse slightly accelerated. The pain was said to be present constantly, but there were paroxyms during which my patient suffered most excruciatingly. Was it colic, produced by undigested food? Her supper had consisted of an oyster-soup with crackers, and her dinner had been light. It might be hysterical, though there were no concomitant symptoms. I administered an emetic of sulphate of zinc, and after emesis gave a large dose of asafetida with no effect. Having failed to get at the origin of the trouble, I treated her symptomatically with morphia and atropia, and after giving nearly a grain of the former, with one-quarter grain of the latter, the pain diminished. I cannot say just why I thought of worms as being the cause of the patient's sufferings, but there being nothing in her condition contra-indicating a vermicide, I began administering the fluid extract of spigelia and senna in drachm doses, and before noon of the next day had dislodged some twenty to thirty lumbricoid worms, with total and prompt relief. This woman is the

mother of five children, and her labors have all been severe; yet she told me that the "cramps" in her abdomen during that night were the most severe pain she had ever experienced.

Case II.—I have had two experiences with this patient. About four years ago she had a severe attack of colic, which was relieved only after she had passed fifty to sixty worms. The second attack occurred recently.

Mrs. N., German, a hard worker; she does washing. Her food is probably none of the best; she seldom eats meat, and lives chiefly on vegetables, bread and tea. Her daughter called at my office on the morning of March 15, saying that her mother had great pain in her belly. I sent one-quarter grain of morphine, and, suspecting the cause of the pain, also ten grains of calomel and one grain of santonin combined, with instructions to take it in half an hour after the the morphine. I was called during the afternoon, and found the patient vomiting; she had retained neither of the powders, and was in great pain. The abdomen was soft; no fever; tongue coated. One-eighth grain of morphine was administered hypodermically, and minute doses of calomel were left, with directions to take them in a little sugar, dry, on the tongue, every fifteen or twenty minutes. I saw her again about midnight; she had not retained a particle of the calomel. The morphine had given her some relief during the afternoon, but the pain in her abdomen was now most intense, the patient writhing and twisting as I have seen those do afflicted with biliary or renal calculus. She was vomiting quantities of a dark greenish fluid. She was then given an injection of hot soap-suds containing turpentine and castor-oil. Almost immediately her bowels acted, and three large, round worms were expelled. One-eighth grain of morphine was then given hypodermically. Early in the morning of the 16th I found her still suffering pain and vomiting the same greenish material. All attempts to administer anything by the mouth, even a teaspoonful of water, were followed by retching and vomiting. Morphine was again given hypodermically, and another enema of soap-suds with turpentine and oil; the latter brought away two more worms. During the day she had three-eighths of a grain of morphine in divided doses, hypodermically, and her bowels moved spontaneously, and there were five more worms in the ejecta. On the morning of the 17th I found no improvement to speak of in her symptoms. I then gave her a quart of a strong infusion of the root of spigelia and senna leaves by enema, and managed to get her stomach to retain two pills, each containing one-half grain santonin and one-half grain calomel. During the afternoon she passed twenty large worms, none of them less than eight inches in length. The symptoms now became somewhat ameliorated; the pain subsided so much that one-eighth grain of morphine, hypodermically administered, at 9 P. M., brought comparative rest for the night. The next morning, March 18, she took two drachms of the fluid extract of spigelia and senna, and during the day passed forty more large worms. Her pain now ceased, and in a few days she was herself again.

TREPHINING AN INFANT.

BY WALTER H. PARCELS,

LEWISTOWN, PA.

Something less than a year ago I was called to see a child, aged exactly seven and one-half months, which had been injured by a carriage rolling down an embankment.

The child's head had evidently collided with a stone. I found at the right parietal prominence a depression of the skull. There was no wound of the scalp, and the child's general condition was not greatly alarming. There was only *slight* tendency to coma, and its vigorous crying showed that "life's fitful fever" was not likely to end immediately; however, the cavity formed by the depressed bone was formidable indeed. It was by actual measurement 3 inches by 2¾ inches in diameter, and rather more than an inch in depth.

The skull being very thin, of course there was no fracture, and I need only to spring it back to its normal position. How could I do this? But little force would be required, provided that force could only be applied as a *vis a tergo*. While at my office for a trephine I slipped a gimlet in my pocket.

Drs. Dean and Atkinson kindly assisted me in the operation, which consisted in first exposing the bone by a T-shaped incision through the scalp. At the very bottom of the cavity I inserted the gimlet and pulled.

I was able to apply a considerable force in this manner, but not enough to elevate the bone. With the trephine I removed very carefully a small button at the same point.

I found a small opening through the dura mater from which oozed a watery substance. This hole had probably been made with the gimlet. With an elevator now applied behind the depressed bone I succeeded in

springing it back to its normal position. It flew back with an audible sound.

The wound was sponged out with strong carbolized water, closed with sutures, and for the next three or four days kept wet with cloths wrung out of carbolized water. No pus formed during the process of healing.

There was no fever, in short there was nothing to indicate that the child had undergone an operation. *Query:* was there a *better* way to elevate this depressed bone?

ADDRESS BY J. M. DA COSTA, M. D.,

AT THE DINNER TO DR. D. HAYES AGNEW,[1] APRIL 6, 1888.

Fifty years ago, on this very day, there stood, with the honors of a University just received, a young man on the threshold of his life. His thoughts were the pleasant ones of the occasion; his aspirations had hardly taken shape; he was the popular comrade of the hundred and fifty-five whose real life, like his own, was to begin. Fifty years have passed, and their Agnew has become our Agnew of the many thousands of the American profession.

Honored Guest:—In addressing you tonight I feel that I speak not simply for those who are gathered around you, nor for those in this Commonwealth whose interest will centre here, but for the whole profession who hold you in such esteem, and whose sympathetic thoughts, could they reach you, would come to you in messages of such goodwill and affection as to overwhelm you with their warmth.

Your career has been, indeed, a remarkable one; and you must pardon me, and let the occasion be my excuse, if in your presence I allude to its success, and to the main causes of that success. Nor is it wholly unfitting in one to do so who has known you and watched your progress with friendly interest almost since you came to this city, to try your powers in a wider field. The training you brought with you as a rural practitioner of note was indeed valuable. Self-reliance, cool judgment under difficult circumstances, are not the least reward of a country physician's hard life. You enrolled yourself as a teacher of medicine in its most laborious branch, and fittingly took charge of a school which has been the nursery of famous anatomists and surgeons,—where Godman's practical skill was displayed, and Joseph Pancoast laid the foundation of that intimate knowledge of the human frame which made him afterwards so great a surgeon.

This Philadelphia School of Anatomy, in College Avenue, has indeed left its mark in the history of medicine. It has been to us what the Windmill Street School was to the London of William and of John Hunter, of Hewson, of Cruikshank, of Baillie, of Benjamin Brodie, of Charles Bell. Its rickety structure harbored not only anatomists—some of them your own pupils, who were to succeed you as celebrated teachers—but its dingy walls heard eloquent discourses on diverse branches from more than one of your future colleagues; in its garret, independent and fruitful researches on the textures of the body were pursued; in its cramped lower room, physiological experiments were carried on, which have made their deep impress on the science of our day.

For ten years' working in this school of anatomy you lived laborious days and nights, and in its stern training your classes grew, until the narrow quarters would hold them no more, and you became the popular, admirable teacher you have proved yourself since, on a larger scale and on a different branch, as Professor of the Principles and Practice of Surgery in the famed University with which your reputation is forever identified. You learned to present facts plainly and impressively, to teach Nature's truths with Nature's simplicity, and without a deadly paralysis of words.

But in these ten years of unremitting work you did something more than teaching. You laid by exact knowledge, by steadiness of purpose and affability the foundations of that large practice which you have since enjoyed, developing every day, more and more, into the trusted surgeon whose deft hand and cool judgment caused his advice to be generally sought. Every country shows in its professions the national traits. You certainly represent as a surgeon, besides much skill, the American characteristic of resolute commonsense.

You have been tried in many a hard case. In none harder, than when your reputation caused you to be selected among the counsellors at the wounded couch of one for whose relief millions were anxiously watching. That in these trying times you bore yourself with the same calmness and dignity we know in you, every one in these millions recognized.

Your success as a surgeon of great repute must, indeed, have been gratifying to you. Not only for the opportunities it afforded you

[1] Given by the Medical Profession, in honor of the fiftieth anniversary of his entrance into the profession.

of doing so much active work in your profession; not only because it gave a personal value to your writings, especially to your opinions expressed in your elaborate work on Surgery; but because it enabled you to carry out a plan of action, of which I may not speak,—one which showed you to be possessed of the same high sense of honor for which Sir Walter Scott has received the unbounded admiration of mankind.

May you, dear sir, who have these many claims to distinction and esteem; may you on this, the fiftieth anniversary of entrance into a profession which you have graced by your industry, your sagacity, your skill, your character; may you accept the homage of those who are engaged with you in the same pursuit as a sign of widely-felt regard and appreciation. May your vigorous frame preserve your power of doing good, of teaching truths, for many a long year. May there always remain with you the assurance that, as age gently lays its hand on you, the chilling finger of time will not lessen the respect, nor benumb the tenderness of feeling, with which old and young alike regard you.

ON THE FORCIBLE FEEDING OF THE INSANE.[1]

BY DR. JULIUS RADER,
PHYSICIAN TO THE NIEDER-ŒSTERREICHISCHEN LANDESIRRENANSTALT AT YBBS.

Translated by A. H. P. Leuf, M.D.,
University of Pennsylvania, Philadelphia.

The following sketch of a fasting insane patient may be of general interest.

A. B., aged 39 years, single, formerly a wage-worker, is said to have been much neglected in childhood and to often have lived off food-refuse found in the streets. She is credited with having been addicted to various excesses, and was admitted to a Vienna hospital suffering with syphilis, where she disclosed symptoms of insanity, leading to her being transferred to three other institutions, of which the last was the Versorgungsanstalt at Ybbs. Here she remained rather apathetic till July, 1882 (eleven months after the beginning of her insanity), when she developed periods of excitement, during which she would break out in tears and occasionally shriek out the vilest epithets. She believed that she was being pursued and murdered by criminals, replied to no questions, and abstained from all food since September 20, 1882. Five days later she was sent to the Insane Asylum at Ybbs.

On admission she was filled with fear, but replied, though lazily, to questions. In answer to the query as to why she refused to eat, she said, "Because I have taken vitriol."

She is markedly congested, her pupils are very wide, the conjunctivæ are strongly injected, and there is *fetor ex ore*. Upon slight urging she took some food, and after the following day began to eat regularly. Otherwise she is quiet, indifferent as to her surroundings, and sits all day at the same place, and only occasionally talks to herself in an audible tone, scolding certain persons.

On Dec. 18, 1882, her face was markedly congested, she was excitable, says her bowels have not acted for several days, but refuses to take a laxative with the remark, "All will be well again if I eat nothing." Therefore, she abstained till Dec. 28, 1882.

In the following years, there was no appreciable change in her condition. She often had delusions of poisoning, claiming that her food had been poisoned so that she would become costive for a time. She would then abstain from food for from eight to twelve days.

In beginning of April, 1887, the patient again became more excitable, noisy, completely inapproachable, scolded continually, using the vilest expressions when approached or addressed, and also had delusions of poisoning. She abstained totally from all food from the 3d to the 24th of April. But during this time she drank considerable water, after taking which she would produce emesis by running her finger back in her throat. After this she would drink more water and repeat the emesis, and continue so many times during the day. Very bad *fetor ex ore* that fills the patient's whole room, and is readily noticed immediately upon entrance.

Patient took some food from the 24th to the end of April. She, however, abstained again from the 1st to the 16th of May, again drank large quantities of water, which she again expelled by self-induced emesis, lasting for hours. From the 16th of May to the 2d of June, 1887, she daily ate a little clear soup, but refused to take any more substantial food. In the beginning of June there set in an enormous, almost unappeasable, appetite.

The duration of the total abstinence and partial abstinence makes up a period of exactly two months. During this time the patient actually fed for only six days; the soup that she took daily from May 16 to June 2 can hardly be considered as food in any strict sense.

[1] Read before the Philadelphia Neurological Society, March 26, 1888.

The formerly very good-looking patient of finely nourished appearance had at last a sickly appearance, a dirty yellowish brown complexion, she was enormously emaciated, very weak, always sat crouching in the same place; during the later period was ever unapproachable, irritable and dejected, and scolded at once upon being approached. Weighings could not be undertaken.

Despite the long abstinence and the bodily deterioration of the patient therefrom resulting, in accord with the Director of the Institution, Dr. Langwieser, I did not proceed to to the artificial feeding of the patient.

The fact, on the one hand, that the patient on repeated occasions remained without food for a considerable time, and then spontaneously returned to food; on the other hand, the most sad experiences that I have had in the forcible feeding of patients during the last six years, gave me the courage to maintain a position of observation.

The question as to whether in a given case forcible feeding should be resorted to or not, is at the present time, despite good work in this direction, not yet ripe for discussion. At all events, the request for the forcible feeding of *every* abstaining patient after a given time, must be denied. Generalization is here least of all in place and every case must be accurately individualized.

The fear that these abstaining patients will die at the end of a week is unjustifiable, when we reflect upon the experience of the modern hunger artists or fasters. According to my experience, never to resort to forcible feeding of the abstaining insane, would entail less damage than the forcible feeding of all such cases. After having seen that many patients follow forcible feeding by violent emesis, and too often die of "Schluckpneumonie," due to the inspiration of vomited matter; and on the other hand, that patients, despite the ample ingestion of food that has been forcibly introduced, fail to assimilate it, and in a short time become enormously emaciated and eventually die, anyhow, not to mention those cases in which death results directly during the forcible feeding (partly because of the fault of a clumsy operator, etc)—these negative results must seem serious and be a cry of warning.

For the sake of comparison it may be well to say that at the present time forcible feeding of the insane is not much different from the not yet very distant past when these patients were much restrained. There was a time when the iron chain, with which the excited patient was fastened to the wall of a cell that in every way burlesqued all sanitary requirements, belonged to the necessary instrumentarium of the "expert in insanity;" and not far in the past is the time when it was considered urgently necessary to confine each new patient, whether quiet or not, in a straight jacket, or to apply it to excited patients for purposes of discipline.

It has taken a long time until this medical treatment was dropped in the service of true humanity, and restraint was resorted to to urge them, when other means were inefficient to prevent injury to the patient.

The danger to the abstaining patient consists in nothing but that of death from inanition; and so the only question to be considered is how long can the patient exist without food? One would believe that the diminution of the body weight might be sufficient; but the insane often overturn all theories and stand a loss of forty per cent. of the body weight without reaching the border of inanition. This then will not settle the question and other means must be resorted to for an answer.

We can only determine this, however, after more material has been studied from different standpoints, and especially that which considers the *etiology of abstinence*. Especially would it be necessary to consider the innervation of digestion that might, besides giving rise to indigestion, also cause hallucinations of taste and therefrom resulting delusions of poisoning, in which cases, because of the digestive power being dormant, forcible feeding could only do harm.

In the second place, there would have to be considered actual anatomical changes of the gastro-intestinal tract, as well as combinations of disturbed nervous innervation with pathological changes of the digestive tract.

Our case seems to be one of this kind. The behavior of the patient during her abstinence in filling her stomach with water and then emptying it by means of self-induced emesis, can be considered as perfectly rational and reminds one forcibly of the washing out of the stomach in cases of gastric catarrh.

It is certain that her own treatment did her more good than if she had been forcibly fed by means of the elastic-tube per nasum. —From the *Wiener med. Presse*, February 5, 1888.

—At the meeting of the Académie de Médecine, March 13, 1888, Dr. Lusk, of New York, was elected a Foreign Correspondent in the section of Surgery, by forty-two votes out of fifty-three. Sir William MacCormac received nine votes, and Mr. Victor Horsley, of London, two.

THE FORCIBLE FEEDING OF THE INSANE.[1]

BY JOHN B. CHAPIN, M. D.,

PHYSICIAN-IN-CHIEF OF THE PENNSYLVANIA HOSPITAL FOR THE INSANE.

The case which has been presented in the paper of Dr. Rader seems to be that of a person who, from some delusion, imposed upon herself periods of fasting extending, in one instance, to twenty-one days, during the years 1881 to 1887, inclusive, and for reasons which seemed good to the physician no forcible means for administration of food were resorted to. The study of this case leads Dr. Rader to question and condemn the practice of forcing food upon insane persons who will not eat, which he holds to be not only useless but dangerous, in which opinion the tenor of an editorial recently published in a medical journal concurs.

Every case of disease out of the ordinary course of experience has a lesson. If the physician in this case came to the conclusion that no great harm would arise if forcible means were not used to break the fast, he probably acted as the large proportion of physicians would or might act, and so far was justified in the wise course that he took. Fasting was quite the normal condition of this person, for she had accustomed herself to abstention from food at different times over a period of six years certainly, and there was no occasion to view her habit in this respect with alarm. If Dr. Rader had been accustomed to use forcible means whenever a patient refused to take food for a brief period, he might have obtained from his experience in this case a new and useful lesson, which others might wisely heed if they are too ready on all occasions to use force to feed an insane person. If he had not been accustomed to promptly administer food when refused by the insane, he might have fortified his radical conclusions by the citation of sad experiences, rather than by appealing to our fears and apprehensions.

First. "As to the question whether forcible feeding is not absolutely imperative in some cases," I must answer it from the standpoint of hospital experience alone in the affirmative. Eighty out of every hundred insane persons present the visible evidences of a lowered state of the physical health, ranging to extreme exhaustion, due largely to impaired nutrition, poor food and little of it. One of the marked changes in hospital practice in recent years, based on good experience and good results, has been the liberal administration of food as the most effectual means of restoration. About the question of alimentation in all of these cases no difference of opinion has arisen, and it is not presented in the paper of Dr. Rader; but what shall we do if the patient persistently refuses food, and in the judgment of the physician it is essential to the preservation of life and for mental recovery that the patient should take it. Shall we be content to do nothing more than to advise and urge the patient, or shall we resort to force? Here we must consider the fact that the patient has been placed under care because he is no longer competent to judge for himself, his mind is disordered, he is dominated by his delusions, and that the disordered condition may be mainly due to the impoverished state of the system. He is no longer competent to determine what and how much food he can or ought to take, what medicine should be administered, or what should be the management of his case. Yet he has certain rights, among them the right in his disordered mental condition to have his case wisely judged by his physician. Because of his insanity and his delusions, the insane person is deprived of his liberty that he may not endanger the community; so the insane are sometimes dangerous to themselves, and are placed under private care or hospital care that the strong will of another person may be substituted in place of a disordered will, and the responsibility of the case must be assumed by the physician, who cannot share it with the incompetent patient. The physician in general practice is sometimes confronted with this very problem in the management of his delirious cases, with absolute refusal to take food when considered essentially necessary, and I have never heard of the question being raised as to the propriety of the use of sufficient force to administer it in critical emergencies.

The term "forcible feeding of the insane" is not to be understood as always meaning the use of mechanical devices for this purpose (of which I do not propose to speak in detail), but it means the application of sufficient force (and not more than sufficient) by the physician, and under his sole direction and supervision to overcome the resistance of the patient, if resistance is made, and if not made, as it is not in the majority of cases, still to administer the required nourishment, notwithstanding the protests of the patient.

[1] Remarks made at the meeting of the Philadelphia Neurological Society, March 26, 1888, in the discussion of a paper by Dr. Julius Rader (see p. 498.)

In the hospital with which I am connected, I find that fifty-three patients have, at some period of their insanity, been fed because they refused food, and it was considered essential to the preservation of life or recovery that they should take it. Of the whole number, eight were fed with a nasal tube, and the remainder with a feeding cup or other simple device. The mental condition or delusions which seem to explain the refusal of food in these cases are presented in the following classifications:

General unsystematized delusions; and refusal to take sufficient food to sustain life, from obstinacy or absolute indifference;

Melancholia—refusal to take food to end life;

Melancholia with stupor and obstinate refusal of food;

Delusion—that patient was immortal and could live without food;

Delusion—That stomach and abdomen were full, and could not hold anything more;

Simple mental and physical enfeeblement with incapacity for self-administration of food or self-preservation.

Other reasons are sometimes assigned, and among them the alleged sufferings which food, taken into the stomach, produces, which deserved consideration, but I have assumed that the presentation of an actual experience would be more acceptable.

The patients embraced in these classifications may be grouped in two classes. We may place together those who from mental enfeeblement had not the capacity of self-preservation; they had no delusions, no mental activity, passions or desires, little vital force and a low form of animal existence.

They swallowed liquid food when placed in the mouth, sometimes resisting and sometimes not. Included in this group are cases of melancholia with stupor, who resisted whatever was proposed—they were silent—resisted the efforts to dress and undress, and refused food. They acted under the influence of delusions, the nature of which was not always manifested. Other cases of an opposite condition are placed in the same category—cases of mania that show great mental activity—ideas being formed with such rapidity that the patient's attention could not be sufficiently aroused and held to take food voluntarily, being too busy to eat, or they refused by reason of hallucinations of the senses of smell, taste and sight.

In the second group are placed those who refused food for suicidal purposes—those who entertained delusions of immortality—that life could in some way be sustained without food; delusions that food was poisoned; and delusions that the stomach was full and could hold nothing more.

None of these patients were fed after a single refusal to take food when offered, nor for the reason that abstinence from food was a violation of a hospital rule to which forcible compliance would at once be required. Not one was forcibly fed until the fast had continued from twenty-four to forty-eight hours, or even longer in those making the second class. When food was administered it was given because the actual exhaustion, as determined by the state of the pulse, tongue and history of the case was so great that life was imperiled, or when a state of delirious mania or melancholia with delirium was supposed to be due to exhaustion from want of food. In every case medical considerations alone decided the administration of food, and the physician acted as he always must act when grave responsibilities are laid upon him, according to the best of his judgment—more than that he cannot be expected to do.

It must be borne in mind that of all the abstainers, but eight were fed with a nasal-tube. The remainder took food from a feeding cup or otherwise, with some or no resistance other than holding the head and hands.

For thirty-five years I have either fed or directed the feeding of patients as seemed necessary, and I believe I speak within bounds when I assert that I could number by hundreds the patients who under my own observation, had recovered under forcible feeding, and that I have erred too often I fear in not commencing forced alimentation sooner than I did. Neither do I believe my observation and experience are exceptional, but the general rule, and what else have we on which to found a system of medical practice but experience? In view of these results which I am sure others will confirm, what warrant is there to condemn forced feeding as useless or dangerous. Physicians and surgeons are always taking chances, and must do so, and sometimes a patient has died under the influence of ether, yet no one will be bold enough to assert the practice of surgical anæsthesia is both useless and dangerous. Whatever may have been the experience of others, I have never had any unpleasant result or complication follow forced alimentation. Some years ago a suit for damages was commenced by a patient in a neighboring State, who alleged that the soft palate had been lacerated by a spoon in the hands of an attendant who was engaged in feeding her while under treatment in an asylum.

As to the time when feeding should be commenced, Dr. Tuke, in a paper read before the British Psychological Association, expressed the opinion that it should not be delayed more than twenty-four hours. Dr. Gray, in his practice, fixed the same limit. As to the general sentiment in the profession, I might here add that Dr. Savage, Dr. Clouston, Dr. Blanford, Dr. Spitzka and Dr. Sankey in their books, advocate the practice of prompt feeding and the administration of plenty of food. Dr. Westphal, of Berlin, and Prof. Ludensdorf, of Vienna, in their lectures, advise their students to resort to forced alimentation when necessary, and show to their classes the devices for this purpose. The French and Americans have expressed themselves in the same direction repeatedly in the medical literature of their countries.

Second. "Are there cases in which forced alimentation is not imperative, although patients refuse to take food?" To this question an affirmative answer is made. Occasionally we have to do with a patient who has some fixed delusion, is generally suspicious and apprehensive, but otherwise perhaps quite rational; there is no disorderly conduct; the general health is fair; and it may, on the whole, be the wiser course to let him alone intelligently, and not to interfere too actively with his individuality, trusting to the separation from home, and the influence of new environments to work some improvement. The delusion may have relation to the patient's food and lead to partial abstinence or complete abstinence for long periods. The patient will appear to be strong, and the mental vigor is not weakened. Here the question will arise whether or not more harm than good will come from the use of force to feed the patient —whether force may not sometimes unnecessarily aggravate or intensify suspicions and delusions, and I think we wisely refrain, in such cases, until a more positive medical indication occurs. I will briefly state a case that was under my care a few years ago, which furnishes a practical illustration of the affirmative of the second question. A clergyman, exhausted by his parish work, became melancholy—was regarded suicidal, as he meditated suicide and made one attempt. After admission to the hospital he seemed much concerned about the supposed failure of his clerical work. He spent several hours daily upon his knees, praying in an audible tone, and imposed upon himself brief fasts, until at last he partook of food but one day in the week, so far as the physicians were aware. No persuasion made any impression upon the patient. He entertained the delusion that only through a mortification of the flesh could he again obtain the favor of God and make good his repentance. He was resolute, conversed calmly, and when it was intimated that force might become necessary, begged that it might not be resorted to. Abstinence from food, partial and total, had now continued for a period of four months, and the question of the use of force was the subject of daily discussion and anxiety. At the end of this period a clerical consultation was had and a clergyman visited him daily. The force of the delusion at length abated and food was taken on alternate days, and afterwards daily and freely, with the result of gradual improvement and complete restoration. This gentleman has now been engaged in his ministrations to a large parish more than twenty years. I have never regretted the conservative course that was pursued in his treatment, and have had repeated evidences of his friendship and confidence, which is not always the case in our relations with the insane.

The answers to the two questions which the paper that has been read seem to suggest, go to show that no absolute rule can be laid down for our guidance in every case, but that we must apply to each our experience and best judgment. I have purposely refrained from any allusion to the medical treatment of conditions in which delusions are present, the removal of which would change the repugnance to food which so often exists, but have confined myself to the question suggested by the paper which has been read.

—Dr. Seavor, director of the Yale gymnasium, has just completed the physical measurements of the sophomore class, and has developed some very interesting facts concerning the effects of training. All but four of the class have made decided physical progress during the year, although only a small proportion of the class have taken a regular course of training. The most noticeable increase in the measurements have been in height, girth of inflated chest and girth of head. A very notable example of the effect of light exercise is in the case of a man who, during the year, without the aid of any regular course training, has developed more than any one in his class. His gains have been: In height, 1½ in.; chest, 2 in.; calf, 1 in.; biceps, 1½ in.; forearm, ¾ in.; breadth of shoulders, 1¼ in., and in the capacity of lungs, 40 cub. in. Three have given up tobacco during the year, but the smokers are 5 per cent. in excess of what they were last year.—*Ledger*, February 24, 1888.

Society Reports.

PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated Meeting, March 26, 1888.

The President, S. Weir Mitchell, M. D., in the chair.

In opening the discussion upon the subject of the

Forcible Feeding of the Insane,

introduced by the translation of Dr. Rader's paper[1], and by the paper of Dr. John B. Chapin,[2]

Dr. S. Preston Jones, of the Stockton Sanitarium, Merchantville, N. J., said he had never seen any serious results from forcible feeding. He found it necessary in about one out of every one or two hundred cases. Some patients refused food because there was actually no appetite and a loathing of food. These patients were in bad health, and in such cases forcible feeding he thought did harm and the patients would mostly die at any rate. If the patient was in good general health and refused food, he did so because he thought that it was poisoned. It could be forcibly administered, and digestion as a rule was good. He had seen such patients steadily improve under such a course and sometimes get well. Patients sometimes had queer reasons for refusing to take food. One man under his care had told his wife as she was about leaving him, that he would never eat a mouthful in the hospital. We let him go for a week or ten days and then began to use the stomach-pump. He soon began to improve and would have gladly taken food had it not been for the fact that he had made a vow not to eat voluntarily. At the end of three months he left the institution restored to health. Another of our old patients was very fastidious about his food and unless he got just what he wanted he would not eat. This became troublesome and on one occasion we used the pump, not in the gentlest manner. And there was no further trouble.

Formerly the stomach-pump and tube were used, but he now employs the nasal-tube. This was easily done, did not injure the œsophagus or stomach, and the food passed into the stomach much more slowly than with the pump. He thought that possibly some damage might be done by pumping a large quantity of fluid rapidly into the stomach. The use of the stomach-tube was sometimes done in a rough matter, causing much discomfort. The mouth had to be forcibly opened, and sometimes this was a serious matter.

Dr. Jones had never before heard of a patient being strangled under the operation. He thought that formerly patients were often forced to take food too soon. At one time it was taught that the patient should not be permitted to go more than one or two days without taking food. He now had a patient who was rapidly recovering, who had been fed twice a day for six months. He had not the slightest doubt but that he would have died if he had been left alone.

Dr. E. N. Brush, First Assistant Physician in the Male Department of the Pennsylvania Hospital for the Insane, said that it had been his habit for the past ten years in the two hospitals with which he had been connected to use forcible feeding. He had employed the nasal-tube, the stomach-tube and injections. He had never regretted feeding a patient, but had sometimes regretted that he had not done it. He thought that sometimes patients were not fed soon enough, and not often enough when we do feed them. In some hospitals the routine custom was to feed two or three times a day. He thought that in some cases it would be better to give smaller quantities six or eight times a day. It was an easy thing to use the nasal-tube, or if there was some deformity of the nose, or other reason contra-indicating its use, the mouth could be readily opened if we went about it in the right way. It had been said that if the patient was a lady, the best plan was to get her to talk. In other cases, the index finger could be passed between the cheek and the teeth and inserted behind the last molar, and the jaws could then be separated.

The importance of this matter should be impressed on the general practitioner. We frequently see cases reported in the newspapers where death has resulted because artificial feeding had not been employed. Physicians had a fear of this simple and ordinary operation. He frequently used the tube as a siphon, the tube being provided with a bulb by which the flow might be started. A similar arrangement might be used for washing out the stomach in cases of poisoning. The bulb was without valves, these being extemporized by the operator's fingers. In a certain proportion of cases washing out of the stomach as part of the feeding operation—the washing being done some time before the introduction of food—resulted in an improved condition of that

[1] See Reporter, p. 498.
[2] See Reporter, p. 500.

organ and a voluntary resumption of eating.

Almost all of the ordinary articles of food might be given through the tube. Mashed potatoes could be given if mixed with a little milk and some preparation of malt. The same might be said of the farinaceous foods. Powdered beef and other preparations of meat are easily administered.

Dr. Brush on more than one occasion fed patients by the rectum. When the stomach rejects food, or when the injection of food caused pain, this method deserved a trial. He had employed various articles by this method. Some years ago he tried defibrinated blood. It acted satisfactorily, but gave rise to such an offensive odor that it was discontinued.

Various methods had been suggested for the feeding of patients. One of the most striking was that proposed by an Italian physician. He suggested that the food be prepared in the form of a bolus, which was placed in the back of the pharynx, and then an electric current was passed through the neck, causing the mass to be swallowed. He claimed to have accomplished this.

The length of time that a patient can be kept in good condition by forcible feeding probably depended upon the other conditions present. He saw a patient of Dr. Yellowlees, in Scotland, who had been fed daily for six years, and was still in good condition. He had fed a patient for eighteen months. The patient was then transferred to another hospital, where at last accounts she was still being fed. Dr. Westphal preferred the use of a funnel with a stomach-tube. So do some of the other German authorities. Some of the English alienists still use the stomach-pump. Dr. Yellowlees used a bottle with the tube attached to its side, at the bottom.

In the matter of tubes, Dr. Brush's preference was for the soft rubber ones. For nasal feeding he used a soft rubber catheter, with the opening in the end. He had various sizes of stomach-tubes of the same material.

Dr. J. C. Hall, Physician-in-Chief of the Frankford Insane Asylum, Philadelphia, said the ground seemed to have been pretty well covered by those who had taken part in the discussion. He must say that he did not agree with Dr. Rader in regard to the advisability of not feeding. He had never seen any bad results from the practice, and he thought that a mistake was often made in waiting too long before beginning forcible feeding. He should not like one of his patients to go more than twenty-four hours without taking food if he thought his condition required it.

At the present time, they had an epidemic of not eating in the institution with which he was connected. About ten per cent. of the cases refused to take food. He found that one with a good deal of strategy will influence others to follow his example. Some he thought had taken up the matter by imitation. He employed the nasal-tube, although he preferred the stomach-tube where it could be used without too much annoyance, on account of its greater rapidity. He used with this a funnel. The only objection that he had met with was that the patient would occasionally regurgitate the food. He thought that the main thing to be taken into consideration was not to allow the patient to go too long without food. He recalled one case of melancholia in which food was refused under the delusion that it was poisoned. This patient was fed three or four times a day for eight or ten months, and finally recovered, left the hospital and went into business. He has seen many other cases in which the advantages of forcible feeding were clearly illustrated. Dr. Chapin had well covered the ground, and he agreed with him on most of the points presented.

Dr. J. Willoughby Phillips, of Burn Brae, Clifton Heights, Pennsylvania, said that during the past ten years he had had about fifteen cases in which forcible feeding was called for. He had never seen any accident; the only untoward occurrence that he had known of was a convulsion during the passage of the stomach-tube. He had used both the stomach and nasal-tube, and either can be employed with ease if properly managed. He used the tubes simply with a funnel. He had then in charge a lady who had not taken food voluntarily since a year ago last December. The nasal-tube was used twice daily during the entire period. She had not gained in weight, neither had she lost. During the operation the patients should be so thoroughly under control that there can be no possible chance of their injuring themselves or interfering with the operation. This can be accomplished by having plenty of assistance.

Of the foods used in such cases, milk and eggs head the list; with these may be combined beef tea, mutton broth, and strong consommé, vegetables in liquid form, and occasionally extracts of malt and spirits, according to the requirements of the case. When patients are debilitated and run down, prompt and liberal feeding is clearly indicated. His practice was to administer nourishment twice daily, the amount being at least a pint and a half at each meal.

Dr. William Osler said that in general practice he often had occasion to feed patients with the tube. In the course of some years' observation in the post-mortem room, he had seen three or four instances of deglutition pneumonia, such as had been referred to in the paper. He saw such a case not long ago. A girl was admitted to the hospital in a comatose condition, and it was necessary to feed her with the nasal tube. At the autopsy a double deglutition pneumonia was found. It was extremely important that the operation should be properly performed. The tube should be entirely emptied before it is withdrawn, and taken out carefully. In the insane, accident is not so likely to result, for the patient generally coughs the foreign matter from the larynx, but the comatose patient does not recognize it, and the fluid passes into the bronchial tubes.

Dr. E. N. Brush said that the danger to which Dr. Osler referred should always be borne in mind. His invariable custom was to pinch the tube if it was soft, or if it was stiff, to place his finger over the opening while removing it. Dr. Hall had referred to the fact that he had had an epidemic of refusal of food. It was found that if other patients knew that there was a patient being fed with a tube there would soon be other cases, especially among those of a hysterical tendency. A curious fact may be mentioned that many of the cases which refused to eat, would eat if they had a chance to steal sufficient to live upon; and acting upon that, he had often avoided the necessity of feeding, by directing the nurses to leave food where these patients could surreptitiously gain access to it.

Dr. Charles K. Mills said that he regarded the subject of the forcible feeding of the insane as one of great practical importance to general practitioners of medicine, as well as to those who had charge of the insane institutions. When he read in the Medical and Surgical Reporter the favorable editorial comments on Dr. Rader's paper, advocating non-interference when insane patients refused food, he felt that the subject would be an excellent one to bring before an association like the Philadelphia Neurological Society, which counts among its members neurologists, alienists and general physicians. He did not, however, feel that he could add much to the discussion; but he would like to emphasize the importance of forcibly feeding the insane who are treated at their homes, or not in institutions especially intended for such patients. He saw many cases of insanity in consultation, and was frequently called upon to treat such patients at their homes, either alone or in connection with other physicians. He could recall a number of cases of acute mania, melancholia, delusional monomania, and stuporous dementia, in which he was confident that fatal results, or absolute failure to succeed in treatment at home, were due to carelessness or tardiness or indifference as regards forcible feeding. Occasionally cases of hysterical insanity will either intentionally, or in spite of themselves because of their morbid impulses, carry their refusal of food so far that their stomachs will not respond properly to the stimulus of food when given, and serious results will then ensue. He had had under his charge for several years an intelligent young man, but the unfortunate victim of a form of paranoia, chiefly exhibiting itself in abulia, inchoate delusions, and imperative conceptions, nearly all circling about a fundamental delusive idea with reference to the sinfulness of having blood entering in any way into his food. This patient was fed 400 to 500 times forcibly with the œsophageal tube in the course of about two years. Dr. Mills had but little doubt that his life was saved by the procedure; and not only so, but, as the patient himself had more than once declared, the forcible feeding had probably prevented him from passing into a state of acute mania, great excitement having frequently resulted from the terrible conflict precipitated by the struggle between the desire to take food owing to pressing physical necessity, and the resistance to the inclination by which he was delusively dominated.

As to the methods of feeding by force, his experience was in favor of the nasal-tube. As this discussion was intended in publication to cover the subject of forcible feeding, he would close his remarks by quoting from his little book on the "Nursing and Care of the Nervous and the Insane," a few remarks on this subject of nasal feeding: "The number of patients who cannot be fed by the nose is very small; occasionally, however, a patient is found whom it seems impossible to feed in this way, owing to the choking and strangling produced. This may be because of some peculiar anatomical conformation, or some special idiosyncrasy on the part of the patient. Such a patient will choke or strangle with nasal feeding when he will not when the stomach-tube is resorted to. If, when the attempt is made to pass the well-oiled tube through the nostril, resistance is encountered, and if, after a few trials, the tube cannot be made to pass, great force should not be employed by the operator, but the tube should be at once with-

drawn and the effort should be made to pass it through the other nostril. In nearly all cases where special resistance is offered on one side, the tube will pass with ease upon the other, and this, in most instances, is because, if hypertrophies or projections exist upon one side, there will be upon the other corresponding or compensating depressions and enlargements. Sometimes, but rarely, the mucous membrane is exceedingly irritable. After the nasal-tube has passed through the nostrils, it seems to have a peculiar tendency in some cases to drop into the glottis, the patient struggling and attempting to scream meanwhile. Some patients will spit or force the tube out into the mouth; and attendants can sometimes through the mouth, keep the tube, which has been passed through the nose, in position. Occasionally the nose is made sore by the use of the tube, but this is not likely to occur if the tube is always perfectly cleaned and well oiled. If it is of the proper kind; that is, a soft tube, there will be no danger of injuring the parts by breaking or perforating the mucous membrane. In using the nasal-tube, great care should be always exercised to see that at least fifteen to sixteen inches of the tube has been passed before beginning the feeding. This will make it certain that the entrance to the windpipe has been passed. Of course care should be taken to observe that the tube has not doubled itself." He would add one remark, namely: Great care should be taken not to administer the food too hot. He knew of one accident occurring in this way.

Dr. S. S. Shultz, Physician-in Chief of the State Hospital for the Insane at Danville, Pennsylvania, sent the following letter to Dr. Mills as his contribution to the discussion:

Danville, Pa., March 23, 1888.

My dear Doctor:—I give you herewith, as requested by you in your favor of the 17th inst., briefly my views in regard to the forcible feeding of the insane.

1st. Is it ever absolutely necessary to administer food against their will to any class of the insane? Is life prolonged or restoration to reason promoted by such a course of treatment? It must be admitted that this question does not allow a mathematical demonstration either way. It is easy to claim when bodily health is restored or the mind improved under compulsory feeding that this would have happened without such treatment, or when death occurs, or insanity becomes chronic, under the expectant plan that such results were inevitable. In medicine, few problems could be solved by such a method of reasoning. The majority of patients who come into hospitals, from country districts at least, suffer from impaired nutrition. Until there is improvement in the pasty tongue, the want of appetite, anæmia and emaciation, it is in vain to look for improvement in the symptoms of insanity. Impoverishment of the blood seems to be the condition which gives many of the so-called causes of insanity their importance. These may be incurable, as, for instance, the remains of injuries to the skull, or disease of the heart, and yet if the nutrition can be improved and the blood enriched, the mental disorder often for a time disappears. When the insanity is the result simply of defective nutrition, progress towards permanent restoration keeps pace with the improvement of the blood resulting from better nutrition. If this torpid condition of the nutritive functions is permitted to remain a long time, the irregular mental habits become chronic, and the risk of incurability rapidly increases.

This much to show my deep convictions that poor blood plays an important part in the causation of many cases of insanity, and that the prompt correction of this will give the best chances of recovery. A German writer defending the expectant plan, sees no danger in fasting when it is not prolonged over fourteen days without taking water, not over fifty days when water is taken, nor so long as 60 per cent. of the body weight remains. The practice of such a rule or anything approaching its extremes, it seems to me must lead to the sacrifice, not only of the chances of recovery, but of life itself. It can certainly not be the part of wisdom to allow the boat with its living human freight to drift to the very brink of the cataract, without attempting to arrest it at the beginning of the rapids, where it can be done with so little risk.

Insane patients having organic disease of the digestive apparatus as inflammation of the pharynx, or cancer of the stomach, are likely to refuse food earlier and more persistently, than the sane in similar conditions, and the measures suitable for those whose fasting is the result of delusion, need modification for these. The melancholic who fast from religious or suicidal motives, or the delusion that there is no room for food, or that the passages are closed, most often carry their purpose to a dangerous extent, and thwart persuasion, reasoning, coaxing, no matter how skilfully or persistently plied. No rule based on the element of time of fasting is applicable; but as there has

been usually for weeks an insufficient amount of food taken, it is safe to begin the feeding as soon as the purpose of abstinence has shown itself to be settled, and refusal to yield to other resources, and both bodily and mental symptoms become worse. The more the character of the patient while in health was marked by resolute purpose and stubbornness of will, the less likely is delay to be of any use.

Of course food introduced into the stomach in this mechanical and compulsory manner is of less value than when taken at the prompting of natural hunger, but one must choose the lesser of two evils.

Nutritive enemata may answer for a time when fasting instead of being the result of a fixed purpose has its origin in the loss of the feeling of hunger.

Patients suffering from melancholy no doubt most often require artificial feeding, but other forms of insanity may demand the same treatment. When no physical condition can be detected that would justify abstinence, the forcible administration of food should not be delayed to the point of starvation in any form of disease. When emaciation has surely set in, the breath has become characteristically heavy and foul, and the strength is diminishing, active measures should be no longer postponed, when the will of the patient cannot be persuaded.

With reference to the manner of carrying out the indication, little need be said, as the nasal-tube is now universally preferred to that by the œsophagus. It has the advantage of making resistance less possible; and injury to the teeth and soft parts cannot occur.

It is possible that the tube may enter the larynx through an awkward position or movement of the patient. If the tube is pervious and haste is avoided such a misadventure will be defeated through the restlessness of the patient and the escape of the air through the outer end of the tube.

Very truly yours,

S. S. Shultz.

—There is a hospital in Chicago which contains the following article in its constitution:

"All medicines used in the hospital must be prepared without alcohol, and all physicians accepting positions on the medical staff of the hospital or dispensary must pledge themselves not to administer alcohol in any form to any patient in the hospital or dispensary, nor to call in the counsel for such patients any physician who will advise the use of alcohol."

Periscope.

Embolism of Right Axillary Artery Connected with Mitral Stenosis; Gangrene of Forearm.

At a meeting of the Clinical Society of London, January 27, Dr. Burney Yeo related the case of a woman who was admitted under his care into King's College Hospital in December, 1886, with great pain and loss of power in the right hand and arms, which came on suddenly, accompanied with giddiness. The fingers, hand and forearm on the right side rapidly became white, and motion and sensation were completely lost. She had had acute rheumatism, and suffered from dyspnœa on exertion. No pulsation could be felt in the radial, ulnar or brachial arteries in the right side; pulsations could, however, be felt in the subclavian. The cardiac action was rapid and irregular, the impulse and sounds were very feeble. The patient also suffered from cough, dyspnœa and great restlessness. In a few days the forearm became blue and mottled, subsequently black, and dry gangrene set in. Opium was given to allay the severe pain and restlessness, and iron, quinine and digitalis to improve the cardiac tone. As the ventricular contractions improved in force and regularity, a distinct, though feeble murmur could be detected which appeared to precede the impulse. After consultation with Sir Joseph Lister it was determined, as soon as the cardiac tone had sufficiently improved from the administration of digitalis, to amputate. This was done, about the middle of the upper arm, by Sir Joseph Lister, under chloroform, on January 14. The patient recovered well from the operation, but two days afterwards pneumonia with pleuritic exudation occurred on the right side, and she died somewhat suddenly on the 19th. *Post-mortem* examination showed considerable constriction of the mitral valve, and a large, old and firm clot in the left auricular appendage, from which, no doubt, the embolus in the axillary artery proceeded. Hemorrhagic infarctions were found in the right lung, and considerable effusion of serous fluid and lymph in the pleural cavity, and on the surface of the lung. The kidneys also contained old, small white infarctions. Examination of the stump showed the primary clot to be situated just at the beginning of the axillary artery. Dr. Yeo added some comments on this case and its management.—*British Med. Journal*, February 4, 1888.

Normal Course of Puerperal Temperature.

The *Practitioner*, February, 1888, publishes the report of a Committee appointed by the Æsculapian Society to study the normal course of puerperal temperature. The report concludes as follows: The deductions which may be drawn from these investigations seem to be that in a large number of cases, as we should expect would be the case in a purely physiological act, labor and the lying-in period are free from any marked fever; but that at the same time the whole system, and especially the mental system, is in a state in which it is very ready to receive impressions from without, and that any reflex irritation or any mental excitement causes a rise in the temperature which may be most marked, but which ceases on the removal of the cause.

Photoxyline in Surgical Practice.

Von Wahl (*St. Petersburger med. Wochenschrift*, No. 20, 1887), says that a five per cent. solution of photoxyline, in equal parts of alcohol and ether, can be differentiated from collodium by the following properties: 1. Persistent firm adhesiveness to the skin. 2. Absolute imperviousness to fluids. 3. Uniform compression of the tissues.

Photoxyline is suitable for: 1. Minor operations among walking patients. 2. Plastic operations upon the face and in the neighborhood of the male genitalia. Over wounds closed with sutures there is placed a thin layer of absorbent cotton saturated with photoxyline. In children, where the soaking of the dressing is not to be avoided, this painting proves a sure antiseptic protective. 3. For laparotomy, any further dressing of sutured wounds is superfluous, and the belly-wound is secured in the best manner. — *Deutsche med. Wochenschrift*, Dec. 8, 1887.

Case of Chronic Sulphur Poisoning.

In the *Berliner klin. Wochenschrift*, No. 42, 1887, Eichbaum reports the case of a man 37 years old, who has been using continuously for eight years a sulphur ointment on his scalp, which was affected with a very copious formation of scales. The pomade was employed every second day, and about three and a half ounces are supposed to have been used. The symptoms began with a feeling of stiffness in the neck; the face was pale, and the brow covered with sweat. Both pupils were dilated, and did not react either to light or to an irritation of the skin; the tongue was somewhat tremulous. The head was drawn a little to the right and behind, and the muscles of the right half of the neck, especially the superficial muscles, felt specially hard and tense. By the exercise of repeated powerful movements of the head, the rigidity gradually yielded. The patient complained of pain in the back part of the head, of a disposition to vomit, and oppression in the chest, and slight tenderness upon pressure in the epigastrium. The pulse was 124, and very small; respiration 16. After a rather restless night his condition improved. It was ascertained that the patient had suffered from headaches before, which were subject to exacerbations at irregular intervals. An attack similar to the one just described had occurred some weeks before. Eichbaum supposes that the patient was poisoned with sulphuretted hydrogen, as under the influence of fat and heat a decomposition of the ointment takes place, with the formation of sulphuretted hydrogen. The latter he supposes entered the body in part through the scalp, and in part through the lungs.

The patient was advised to discontinue the use of the ointment entirely, and to take a course of warm baths, abundant exercise in the fresh air, and the like. The symptoms of the disease gradually subsided, and in about four weeks there was no sign of the the disease to be seen.

Phosphorus in Typhoid Fever.

Aycart writes to the *Revista de Sanitad militar.*, July, 1887, recommending phosphorus both as a tonic and as a stimulant. He employs an ethereal solution containing one-third of a grain of phosphorus to one fluid drachm of the vehicle, and prescribes this dose in two parts, taken daily in a glass of Malaga wine. In two cases in which he has used it, he has obtained, he says, satisfactory results. The first case was characterized by an irregular fever, and by delirium and collapse. In this condition, phosphorus within two hours brought about regularity of the pulse, sleep, return of consciousness, and finally, in a few days, the normal course of the disease. The second case is that of a patient in whom stupor was extreme, the fever high, and the course of the disease irregular. Toward the fourteenth day, the temperature suddenly fell 3.8°, and fatal collapse threatened. Aycart then prescribed phosphorus. Several hours afterwards, the threatening symptoms had disappeared; the next day the patient began to improve steadily, and then became convalescent. He recovered. — *Gazette Hebdomadaire*, January 13, 1888.

Tubercular Disease of the Testis as a Local Affection; Desirability of Early Castration in Certain Cases.

The basis of this paper, which was read at a meeting of the Royal Medical and Chirurgical Society, Jan. 24, 1888, was a record of five cases of tubercular disease of the testis which came under the notice of Mr. Wm. H. Bennett amongst his outpatients at St. George's Hospital. The cases were selected with great care from a considerable number of patients suffering from this disease, as they possessed the following important characteristics in common: 1. An absolutely perfect family history, and an entire absence of evidence of privation, excess, or other conditions predisposing to the development of tubercular disease. 2. A perfectly clean bill of health up to the time of the onset of the disease in the testicle. In this respect exception might perhaps be taken to the case of patient No. 5, who had suffered from syphilis twenty-three years previously, but had never been troubled by any symptoms since. 3. The cause of the original inflammation in the scrotal contents was due in all the cases to direct local irritation, traumatic in four, gonorrhœal in one. 4. In each case the spinal column showed evidence of disease before the opposite testis, epididymis, either seminal vesicle, or other parts in the immediate neighborhood of the testis originally involved. The spinal disease was so insidious that, with the exception of case No. 3, in which it was discovered accidentally, its existence was not suspected by the patient. 5. In none of the cases did the affection manifest itself in other parts until after the original disease had broken down. These points were fully discussed, and the following propositions submitted: *a.* Inflammation of the testicle or epididymis, the consequence of injury or direct irritation, might result in tubercular disease of a purely local kind, which if left to itself, tended surely to generalization. *b.* The greatest tendency to general infection was at a time subsequent to the breaking down of the original disease. *c.* Parts remote from the testis originally involved might be affected before the opposite testicle, epididymis, or either seminal vesicle. *d.* The rational treatment of cases like those under discussion was castration, upon the appearance of disintegration about the original disease—that is, at the commencement of what the author termed, for reasons stated, the "dangerous period." Mr. Bennet subsequently explained that he had not meant to imply that what he described was the common course of tubercular disease of the testis, but merely what had actually happened in 5 cases out of about 150, from which he thought there was something to be learnt as to the method of diffusion and the mode of arresting it. The symptoms referred to the spine were beyond what could be caused by inflamed glands. In one case there was carious bone shown at a *post-mortem* examination; in another the spinal curvature was half as large as his fist; in a third the stiffness extended up to the upper dorsal region; in a fourth the spinal symptoms had improved, but relapsed, with spread of the disease to the other testis. Mr. Clutton's case was dissimilar in having a nodule in the cord, whereas his own point had been to advise operation before the formation of a nodule in the cord. It certainly needed some practice on the living and the dead to acquire a thorough practical knowledge of the condition of the vesiculæ seminales and the prostate in health and disease, and he had ventured to bring this subject before the Society as raising the question of the method of diffusion of local tubercule and the opportunities of stopping it.—*Brit. Med. Journal*, January 28, 1888.

Management of Children's Teeth.

Professor Miller, of Berlin, in an article on the milk teeth, published in the *Therapeutische Monatsschrift*, No. 2, 1888, points out the evil effects on the teeth of sugar and other substances which undergo fermentative changes. A child, he says, is constantly eating sugar and substances containing it, and though the particles of food are more likely to get between the teeth and set up caries than in the case of grown persons, children never, or at least very rarely, have their teeth cleaned. He would insist upon proper cleaning twice daily, a very soft brush and a weak disinfecting dentifrice being employed for the purpose. Sweetmeats should be entirely prohibited or their use very carefully supervised. Barley sugar he does not consider so injurious as chocolate and soft clammy sweets, because the former is more soluble. It should be remembered, too, that starchy substances soon become converted into grape sugar. Prof. Miller suggests that after a child has eaten the barley sugar, its mouth should be washed with water. All decayed teeth should be filled at once, even in the case of children under three years of age. All children's teeth should be attended to from the very beginning.—*Lancet*, February 11, 1888.

Case in which there were Numerous Fractures at Birth.

In the *Archiv für Gynäkologie*, Bd. xxx, Heft 2, Dr. Paul Linck reports a case in which there were numerous fractures of intra-uterine origin. The fœtus was expelled in the membranes spontaneously in the thirty-second week of gestation, and died of asthenia 27½ hours after birth. The mother was a primipara, 22 years old. In the left thorax there were about forty, in the right about forty-four fractures. The fractures were in part united with callus. The sternal ends of the ribs were not abnormal. The upper and lower extremities showed ten fractures, of which six were recent, and were without formation of callus; four were older, and in different stages of healing.

Syphilis and rachitis are, he says, positively excluded in this case. A microscopic examination disclosed a deficient calcification of the bone tissue, so the author thinks that the pronounced changes which were present in this case are to be referred to an unknown intra-uterine disease of the bones, with at times softness and fragility of the bone substance. In this softened condition of the bones pressure upon the parts of the child or some movement of its own are, in the author's opinion, the immediate causes of the fractures.

Abortive Cervical Hypertrophic Pachymeningitis.

In a communication to the *Deutsche med. Wochenschrift*, No. 26, 1887, E. Remak states that in a boy 13 years old, motor disturbances of both hands suddenly occurred. There existed bilateral *main-en-griffe:* the proximal phalanges were in a position of hyperextension, the distal bent, the fingers, in a position of dorsal flexion (*main-en-prédicateur*, of Charcot). The median and ulnar nerves in the upper and forearm reacted normally to the electric current, but their palmar extensions reacted badly. The direct muscular excitability was diminished. Besides these symptoms, there were reactions of degeneration, and subjective and objective disturbances in sensibility on the part of the hands. There existed, therefore, a degenerative atrophic paresis of both upper extremities. In addition, a slight spastic paresis of the lower extremities could be demonstrated. Iodide of potash and treatment with the galvanic current brought about nearly complete recovery within two months. The neighborhood of the first to the third thoracic vertebræ was very sensitive. In view of the favorable course of the case, Remak excludes a tumor as the cause, and thinks that the trouble consisted in mild grade of cervical pachymeningitis.—*Centralblatt f. d. med. Wissensch.*, January 14, 1888.

Resorcin in the Local Treatment of Acne.

At a meeting of the Medical Society of the County of New York, Dr. G. H. Fox read a paper on this subject. There were many drugs, he said, used in the local treatment of acne, but he would confine his remarks to the one which in his hands had afforded the best results. It should be stated at the outset that there were very few cases of acne in which local treatment alone would effect a cure. In certain cases ordinary stimulating local treatment was worse than useless. From a therapeutic standpoint all cases of acne might be divided into two varieties, the indolent and the irritable. In the indolent variety, which included about half the cases, there was a doughy, thick skin covered with projecting comedones, papules and pustules. One could in these cases press out the contents of the distended glands without doing any injury to the skin. These were the cases which were benefitted by local treatment. On the other hand, there was perhaps an equal number of cases in which the glands were normal, the lesions being chiefly of a vascular character, with a few red blotches scattered over the face, and a marked tendency of the face to flush after eating and excitement. There were a few comedones, and any attempt to press them out would make the face look a great deal worse. The skin was thin and sensitive. In this class of cases local treatment would not effect a cure, and was apt to make the condition worse; we had to depend upon tonic and hygienic measures. But in the indolent class of cases, in which there was little acute inflammation of the skin, we could use some strong stimulating local treatment to advantage. The sulphur and mercurial ointments and lotions did a certain amount of good, but he thought the treatment with green soap infinitely superior. The chrysarobin treatment, as suggested by Dr. Metcalf, was certainly efficacious, but in his opinion the objections to it more than counterbalanced the objections to the disease. Resorcin he had found equally curative and free from the objectionable qualities of chrysarobin. Resorcin could be applied as a lotion or as an ointment. It caused a low grade of inflammation. Like carbolic acid, it was a mild caustic. Its application was followed by death and exfoliation of the thick epidermis, leaving a thin, healthy skin.—*N. Y. Med. Journal*, March 10, 1888.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record. 7.00

All letters should be addressed, and all checks ana postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

CASTRATION AS A CURE FOR CRIME.

In a paper read before the Cincinnati Academy of Medicine, February 27, 1888, DR. ORPHEUS EVERTS discusses with much force the advisability of what he calls "Asexualization as a Penalty for Crime." From this paper it appears that by this he means the removal of the testicles or ovaries of criminals convicted of offences recognized as likely to be repeated by their offspring. The proposition, in this country, to castrate men convicted of rape is credited to Prof. Agnew, of Philadelphia; but, as Dr. Everts states, the idea is not unlike that said to have been put in practice upon the priest Abelard for having seduced the famous Heloise. This, however, was an act of vengeance, and very different from such an act of judicial protection to society as is contemplated by those who favor castration as a punishment for rape. For in this case the object is not merely to punish the offender and to deter others from imitating his misdeed, but also to prevent him from repeating a crime of which he has shown himself capable. We doubt that it is generally intended, by those who favor it, to be a means of preventing the propagation of men with a predilection for rape.

But Dr. Everts goes much further, and boldly proposes castration as a remedy for crime in general, because it will hinder the begetting or conception of children to inherit the vicious inclinations of their parents. This is, indeed, a heroic proposition; and, while it has much to recommend it to the good opinion of thoughtful men, we cannot think that the time is ripe for its adoption. The argument in its favor by Dr. Everts is strong and deserving of careful consideration; but we think that he overlooks a very important point in the matter. This is that it would be almost, if not quite, impossible to apply the penalty of castration in a way which would commend its use to prudent men.

If it were proposed only for rape and murder, the difficulty would not be so great; because after conviction by due process of law and the lapse of a reasonable time, the infliction of castration would not appear to be a cruel or inhuman punishment. But, in any case, there would be the possibility of an unjust infliction of a very severe and irreparable injury, and—in the case of rape—of driving one who had committed one crime to the commission of another by way of retaliation. For other crimes than rape or murder, we do not believe the community would ever consent to the penalty of castration; because the determination of the individuals to which it was applicable would of necessity rest with medical men, to whom the courts have no disposition to commit their judicial functions. We cannot imagine, and would not advocate, the substitution of any board of medical experts for the organization now provided by law for the determination of the gravity of offenses against the persons or property of the citizens of the United States; and we cannot see how the penalty of castration could be inflicted for any crimes except rape or murder, without the intervention of a set of experts in psychology for whom there is no public desire, and in whom there would be no universal confidence. For this reason we regard the

proposition of Dr. Everts as chimerical, although we think that much might be said in its favor if it were restricted to the two crimes we have mentioned. For rape, we believe castration would be a fit penalty, and we would hope it might prove an efficient one; for murder, it might be adequate, although we have our doubts about this. We do not think it would be an improper penalty for either offense; and would not regret to see its merits tested for awhile at least.

BACTERIOLOGY.

There is a feeling on the part of a certain number of conservative medical men that what is generally known as bacteriology, or the germ-theory of disease, is just now being pushed a little too vigorously by its advocates. We have some sympathy with this feeling, and do not hesitate to say that—like most comparatively new theories—this one has led to exaggerations and even to serious scientific mistakes. But on the other hand we think that a fair respect for gradually accummulating evidence compels the admission that the study of bacteriology has passed beyond the tentative stage, and that it now rests upon a secure and perfectly reasonable basis. This being the case, it is a mistake to scoff at it, or to pass it by with one's ears stopped. It may be that it has unwise and too enthusiastic supporters; but it cannot be denied that it also counts among its supporters a large number of the most earnest, most intelligent and most conscientious students of medical science. It is a factor of the utmost importance in this science at the present time, and ought to be fairly considered by all who are not governed solely by prejudice.

For this reason, it is with some regret that we note the fact that a recent investigation by *Science* demonstrates that a considerable number of medical schools in the United States treat the study of bacteriology with neglect, and some of them even with scorn. Our own position of reserve in regard to certain claims of the bacteriologists makes it fitting that we should ask for them more unprejudiced treatment than they sometimes receive, and that we should call the attention of our readers to the fact that there will be no better way to restrain actual excesses of belief than to coöperate with those whose faith is more unquestioning, in the endeavor to determine the true limits and possibilities of this fascinating study. No good end can be served by simply denying what they assert, and much good may be lost by standing still and saying that it will not amount to much after all. The indications are that before long those who refuse to believe what is reasonable about germs, and the germ-theory, will be either left behind or overwhelmed by the advance of medical science; and we believe that no medical school can afford—for its own sake, or for the sake of science—to neglect the study of bacteriology. Such study may confirm, or it may refute the claims of the so-called bacteriologists; but it is a necessity of the time, and absolutely indispensable to a correct decision as to the exact position to be accorded to this vigorous progeny of modern methods of medical study.

DANGERS OF WATER-GAS.

The College of Physicians of Philadelphia has again exercised one of the most important functions for which it was originally established, and which it so recently exercised in connection with the subject of cholera and National Quarantine Regulations. A proposition being entertained by the municipal authorities of Philadelphia to introduce water-gas for lighting purposes, the College of Physicians appointed a Commission to investigate the scientific and sanitary features of the subject, and on its recommendation has addressed a communication to the Mayor of Philadelphia, in which the dangerous nature of this gas is described, and certain precautions to be used in its distribution and consumption are suggested.

The recommendations of the College of Physicians are entitled to the highest respect, and there can be no doubt, after reading the findings of its Commission, that water-gas is a dangerous compound, and one not to be used except with great care. It may be that the manufacturers of this gas can suggest a way in which its dangers can be avoided, so

that its comparative cheapness may be utilized. Until this is done, however, ordinary prudence would seem to dictate that some other kind of illuminant be chosen for use.

A TRIBULATION OF THE PRACTICE OF DENTISTRY.

In a recent number of the REPORTER we spoke of the appreciation usually enjoyed by medical men in this country, and it is with some regret that we note that so much cannot be said about our brethren of the dental persuasion. It is reported that a dentist of Jersey City has been sued for damages by a woman who grounded her action upon the allegation that he supplied her with a set of false teeth of such poor quality and workmanship that mastication is impossible, and that her digestion has thereby been ruined.

It is painful to reflect upon the unwillingness which dentists will feel to exercise the cosmetic functions of their calling, if this woman wins her suit. To expect a dentist to insure perennial strength of digestion with every set of false teeth, is asking a little too much. It might happen that a woman whose natural teeth were so poor that she would choose rather to have them—or their wrecks—extracted, and to rely upon such substitutes as human skill can construct, would have an inherent tendency to disorders of other portions of her alimentary apparatus, and then the luckless dentist might be blamed because he did not furnish a sound stomach with each set of masticators. It might happen, we say; because medical men have conceived the possibility that miserable teeth may be anything but the outward and visible sign of an inward and spiritual grace.

This being the case, we trust the community may not get into the way of thinking that dentists can supply all the defects imposed by a relentless Providence, or acquired by careless or ignorant human beings. We have no desire to come between an unworthy man and a justly incensed woman, but, as the courts are said to exist for the especial protection of the weak, we trust that when any unfortunate man—dentist or doctor—is charged with malpractice he may not be convicted because any very simple dictate of common sense has been overlooked in judging his apparent delinquency.

MEDICAL "ENGLISH AS SHE IS WROTE."

In a report of the French Congress or Surgeons in Paris, received by the REPORTER within a few days, there are many amusing passages, among which are the following: M. Thiriar, is made to say, of the operation of resection of the ribs: "After having tried all the processes, I am now making my costal amputation by means of a single transversal incision. I can easily take away seven or eight ribs, and I usually obtain a joint at the first attempt."

M. Delorme, is reported as speaking of certain defects of the operation, and adding "But it would be quite otherwise if to the osseous resection were added the vertical section of the inner side in the whole height of the cavity and a compress made of the carneous shreds to bring them into contact with the opposite inner side. If the cavity were extended even beyond the limits of resection, the lateral orifices could be obliterated, and if necessary the inner side compressed and fixed in this position with catgut."

M. Lannelongue is credited with the startling announcement that as early as the 31st of May, 1887, he had "pointed out the multifarious origins of sub-phrenic or epi-hepatic abscesses, and recommended according to their location, either by the simple opening of the inner side of the belly, or the resection of the abdominal portion of the thorax, including the lower edge."

These examples of "English as she is wrote" are too delicious to be allowed to pass into oblivion, and deserve to be placed on record together with those others in ordinary English which have of late afforded so much amusement to American readers. They do not disclose peculiar ignorance on the part of the French writer, but rather the pit-falls which lie in the way of one who makes a venture in a foreign tongue, with that treacherous guide—the dictionary. The errors are not only very interesting in themselves, but also on account of the philological questions which they suggest, and it will afford not

only amusement, but instruction as well, to trace the way in which some of the most striking and ludicrous of them have crept into this report.

FORCIBLE FEEDING OF THE INSANE.

In an editorial of the REPORTER, March 10, 1888, we called attention to a recent paper by Rader upon the subject of forcible feeding of the insane. In this editorial we spoke with approval of the views expressed by Rader, and pointed out some of the apparent dangers of this method, as well as the fact that it might be resorted to when it was by no means necessary.

Our editorial attracted the attention of the Philadelphia Neurological Society, and it took the subject up for discussion at its meeting, March 26, 1888. In this number we publish in full so much of the proceedings of that meeting as refer to the forcible feeding of the insane. From the report which we give, it will be seen that the general sentiment of those who spoke was that the dangers of forcible feeding of the insane are not so real or so great as to counterbalance its advantages. This is not exactly the view expressed in our editorial; but it is one entitled to the greatest respect. Certainly when a number of men who have made insanity a special study declare plainly in favor of what a single expert deprecates, the presumption is that they are right; and the REPORTER, under the circumstances, may adopt the language of Sir Thomas Browne in regard to his Religio Medici, of which he says: "Lastly, all that is contained therein is in submission unto maturer discernments; and, as I have declared, shall no further father them than the best and learned judgments shall authorize them."

NEW USE FOR A STATE BOARD OF HEALTH.

In one of the passenger railway lines of Philadelphia we have observed an advertising sign which states that "The Pennsylvania State Board of Health gives the highest endorsement for purity to Germania bottled beer." We think there must be some mistake about this.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the REPORTER.]

UEBER DIE LEPRA IN DEN OSTSEE-PROVINZEN (ON LEPROSY IN THE BALTIC PROVINCES). I. FLUGBLATT. 8vo, pp. 16. Dorpat, 1887. Printed by K. A. Hermann.

This little brochure has been prepared by Prof. von Wahl, of Dorpat, as a means of furnishing information to the proper persons in Russia in regard to the subject of leprosy, and in order to stimulate co-operation in the work of gathering further information. One of the most important points discussed is that of the infectious and contagious nature of leprosy. This is thoroughly believed in by Prof. von Wahl, who thinks, however, that the disease is contagious only when the lepra-bacillus is liberated from the body which bears it by an ulcerative process. His paper is illustrated with three beautiful photographs, showing one patient with tuberculous leprosy, and two with macular or anæsthetic leprosy.

EIN STUDIE ÜBER DIE LEPRA IN DEN OSTSEEPROVINZEN, MIT BESONDERER BERÜCKSICHTIGUNG IHRER VERBREITUNG UND AETIOLOGIE. Von PETER HELLAT, Inaugural Dissertation. 8vo, pp. 103. Dorpat: K. A. Hermann's Buch-und Noten-Druckerei, 1887.

This interesting thesis, which contains a map and two engravings of microscopic sections of the skin in a case of leprosy, was prepared under the supervision of Prof. von Wahl, who has taken a great interest in the subject. Dr. Hellat's monograph is one which is calculated to be of great service to all students of leprosy, and especially to those who are interested in its history and developments in the Baltic provinces of Russia. It contains a very thorough study of the subject, and the illustrations contribute very materially to its worth.

THIRD ANNUAL REPORT OF THE MANAGERS AND SUPERINTENDENT OF THE NORTH TEXAS HOSPITAL FOR THE INSANE, AT FERRELL, FOR THE YEAR ENDING OCTOBER 31, 1887. Austin: State Printing Office. 26 pages.

The report of the North Texas Hospital for the Insane, it is interesting to note, does not call the institution an "insane hospital." In keeping with this example of correct expression, we find the contents of the report marked by many evidences of good sense. This one contains, among other things, an account of the findings of a number of autopsies—which, the report states, are made in all cases in which the bodies are not claimed for burial—and an account of the efforts made to secure a good library for the inmates of the hospital. On the whole, the managers and superintendent are to be congratulated on the evidence furnished by their report that the hospital under their care is governed according to the best principles of humanity and science.

PAPERS READ BEFORE THE LANCASTER CITY AND COUNTY MEDICAL SOCIETY, AUGUST, 1885—MARCH, 1888. 8vo, paper, pp. 55. Printed by the Society.

It was a good idea for the Lancaster Medical Society to gather into one volume eight of the papers

read before it during the last three years; and the friends of the Society will share the pleasure with which it must regard the products of the brain of its members. One of the most interesting essays in the book before us is that of Dr. John T. Carpenter, who, under the title "Some Things that I have Learned in Medicine," gives an entertaining and Instructive account of the changes which have taken place in medical thought during his lifetime. In addition to this, there are here three reports on surgery by Dr. Alex. Craig and Dr. S. B. Foreman, a paper on Salicylic Acid in the Treatment of Rheumatism, by Dr. J. H. Musser, now of Philadelphia, but a Lancaster county man by birth; a paper on Preventive Medicine, by Dr. D. B. Weaver; a Report on the Practice of Medicine, by Dr. A. M. Miller; a Report on Obstetrics, by Dr. M. W. Hurst and Dr. J. H. Musser; a paper on Two Interesting Cases of Eye Disease, by Dr. D. B. Weaver; and one on Ileo-Colitis, by Dr. G. W. Berntheizel. The whole is very interesting reading and very creditable to the Society from which it emanates.

TRANSACTIONS OF THE HOMŒOPATHIC MEDICAL SOCIETY OF THE STATE OF NEW YORK FOR THE YEAR 1887. 8vo, paper, pp. 132. Rochester, N. Y.: published by the Society, 1887.

The most striking feature of this volume of transactions is the fact that it is very hard to find any homœopathy in it. A large number of the papers are upon surgical and obstetrical subjects, and several of them are upon the treatment of insanity. In one of the latter, Dr. David A. Gorton describes a case of melancholia which he treated with mercury in doses of a quarter of a grain every four hours for three days; and this good old-school dosage called forth no protest. It is a pity that so much that is excellent as is displayed in this volume should not have found a place under the flag of the regular school of medicine, where it rightfully belongs, instead of under that of homœopathy, which has no claim upon it whatever.

Pamphlet Notices.

[Any Reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage stamp.]

THE MEDICAL JURISPRUDENCE OF INEBRIETY. By JOSEPH PARRISH, M.D., Burlington, N. J. From the *Journal of Inebriety*, January, 1888. 7 pp.

AN ADDRESS DELIVERED BEFORE THE CORPORATION OF THE WASHINGTONIAN HOME, BOSTON, MASS., ON ITS THIRTIETH ANNIVERSARY, FEBRUARY 20, 1888. By T. D. CROTHERS, M.D., of Hartford, Conn. 18 pp.

BIOGRAPHICAL SKETCH OF DR. AUSTIN FLINT. By J. M. DA COSTA, M.D., LL.D. From the *Transactions of the College of Physicians of Philadelphia*. Third Series Volume IX. 10 pp.

L'ANTIPYRINE: SON ACTION SUR LA NUTRITION; SES INDICATIONS GÉNÉRALES. PAR ALBERT ROBIN, Membre de l'Académie de Médecine, etc. From the *Bulletin de l'Académie de Médecine*, December 6, 1887. 27 pages.

TRAITEMENT DES FIÈVRES ET DES ÉTATS TYPHOIDES PAR LA MÉTHODE OXYDANTE ET ÉLIMINATRICE. PAR ALBERT ROBIN, Membre de l'Académie de Médecine, etc. From the *Archives Générales de Médecine*, January, 1888. 38 pp.

—Dr. Parrish's pamphlet contains a brief but earnest argument in support of the theory that inebriety is often a manifestation of mental disease, and not of moral infirmity. He uses the inexact expression, "Inebriety the Disease," which is partly responsible for the misunderstanding of the position held by those who share his views, on the part of those who think they are both erroneous and harmful. Men like Dr. Parrish, who have made a special study of the phenomena of intemperance in the use of alcoholic stimulants, ought to know more about it than those to whom it is but an occasional object of study; and—without admitting the soundness of their opinions when pushed to the extremes to which they are sometimes pushed—it must be acknowledged that there is a great deal of force in what they say, and that it deserves at least respectful consideration.

—Dr. Crothers' address gives a very interesting and ably written history of the Washingtonian Home, and incidentally of certain features of the temperance movements in this country since 1859. In addition to this, it contains a very good summary of the steps by which the study of inebriety has come to be so largely one of mental disorders. Dr. Crothers goes back to the ancient records of Egypt and Greece to show that, long before the Christian era, the abuse of alcoholic stimulants was regarded as an evidence of bodily and mental disease, and traces the progress of this opinion in America from the time when, in 1790, Dr. Benjamin Rush, of Philadelphia, discussed it, until the present day. Incidentally, he also makes a plea for a more general acceptance of this opinion, which he believes furnishes the only scientific basis for curing the evils of intemperance.

—Dr. Da Costa's sketch of the life of Dr. Austin Flint is a graceful and elegant tribute to the memory of one of the most eminent medical men and medical teachers of this century. Its brevity is not the least of its merits, and it furnishes an example worth imitating of the way in which a tempting subject may be handled without diffuseness or prolixity.

—Prof. Robin's paper on antipyrine contains the most complete and scientific discussion of the physiological effects of this drug which we have seen. The results of his labors, the full details of which are given here, indicate that antipyrine is to be considered rather as a nervine than as a drug to be used to reduce temperature; and that its best effects are to be expected when it is administered to control nervous excitation and to diminish pain. On the other hand, Prof. Robin shows that antipyrine diminishes the process of oxidation in disintegrated tissues, and ought not to be used in the treatment of diseases in which this process is to be favored. Finally, he describes the antiseptic properties of antipyrine, even when administered in small doses. The whole paper is one of extreme interest and value, not only for what it teaches in regard to the uses of this particular drug, but also as an example of the way in which the effects of any drug may be profitably studied.

—We have already, in an Editorial in the Reporter, February, 25, 1888, called attention to the principles laid down in this admirable paper of Prof. Robin as those which ought to guide the practitioner in the treatment of fevers and typhoid conditions.

As we then stated, he believes, and we think demonstrates, that fevers, and especially typhoid fevers, are to be treated by some method which facilitates or promotes the process of oxidation in the tissues, and of the elimination of the products of retrograde metamorphosis. The argument of Prof. Robin is founded upon careful chemical analysis and clinical observation, and may be strongly recommended to the attention of medical men, and especially of medical teachers.

Notes and Comments.

Contribution to the Etiology of Congenital Syphilis.

In addition to the intrinsic importance of the subject, the question of congenital or hereditary syphilis is one that possesses great interest to the student, because of the many uncertainties connected with it. Syphilographers are now very generally agreed that a syphilitic woman may beget a syphilitic child without infecting her husband, and some believe that a man who is a sufferer from the disease in its later stages may beget a syphilitic child while the mother escapes infection. Although there is little doubt concerning the first of these points, there is, nevertheless, much dispute as to the time at which the child becomes infected. It was formerly held that a woman who did not acquire the disease before the seventh month of gestation would give birth to a healthy child. Chabalier has reported a case in which a woman became infected sixty-three days before the birth of a syphilitic child. But an instance is now related by Dr. F. Sorrentino, in *La Riforma Medica* of December 23, 1887, in which the date of infection was but fifty-two days before delivery.

A woman, 26 years of age, of sound general health, had been married at the age of 20 to a coffee-house keeper, by whom she had had two healthy children born at term. In May, 1886, her husband left her, when she was two months pregnant, and went to Marseilles on business. He returned home on November 14, and had intercourse with his wife at that time, infecting her with a syphilis which he had contracted during his absence. Fifteen days after the primary sore was noticed an extensive roseola appeared, which was treated energetically by subcutaneous injections of mercuric chloride. The child was born on January 5, fifty-two days after the mother's infection. It seemed at first to be healthy, but soon manifested the symptoms of hereditary syphilis. There was no sore about the lips, mouth, or pharynx to suggest the possibility of infection from the mother post-partum.

This case, if all sources of error can be excluded, would appear to demonstrate conclusively that a woman may give birth to a syphilitic child when her disease is contracted later than the seventh month of gestation.—*Medical Record*, March 22, 1888.

A Perfect Insect Powder.

Under the name *Poudre insecticide perfectionnée* a new and very efficacious insect powder has been introduced into the European drug trade. It consists simply of pyrethrum flowers to every 100 parts of which by weight, 1 part of naphthalin has been added. The naphthalin must be in very fine powder and intimately mixed with the pyrethrum. As a great deal of insect powder (in bulk) now found in the market is scarcely worthy of the name, we would suggest that our readers may avail themselves of the information here given, and convert such stock, if they chance to have any of it on hand, into a valuable and rapidly-selling article. A specimen of a powder sold by an itinerant vender to a restaurant-keeper in this city a short time ago, and found to be very efficacious against roaches especially, was on examination by the writer found to consist of pyrethrum mixed with borax in exceedingly fine powder. Borax alone is an excellent blatticide.—*National Druggist*, March, 1888.

Antipyrin as a Hæmostatic.

Dr. W. M. Powell, in a communication to *Daniel's Texas Medical Journal*, March, 1888, says that he was sent for in haste to see a woman who had a frightful hemorrhage from a sore leg which had been struck, and when he arrived he found her nearly exhausted. A four per cent. solution of antipyrin was applied, and he had the satisfaction of seeing the bleeding quickly checked. A light compress and bandage was then applied, and the extremities elevated on pillows in bed. No more hemorrhage occurred.

A few days later he operated on a boy seven years old for phimosis, removing nearly one inch of the prepuce; the hemorrhage was profuse. Before removing the clamp forceps he applied a four per cent. solution of antipyrin, and also immediately after removing them. All bleeding was promptly arrested and mucous membrane and foreskin were neatly brought together with numerous stitches without the least annoyance from further hemorrhage. A simple water dressing completed the operation, and on redressing, the following day, he says he does not think he ever saw a cleaner, nicer wound.

Jaborandi in Hiccough.

In a case of obstinate hiccough which continued day and night and brought the patient fearfully low, all possible means—bromide of potash, morphine, belladonna, galvanism, pressure upon the trunk of the vagus and phrenic—were employed without relief. Küthe, however, secured prompt success from a decoction of jaborandi, 8 parts to 180. The hiccough did not recur.—*Nederlandische Tijdschrift voor Geneeskunde.*

Antifebrin in Hemicrania.

Ott (*Prager med. Wochenschrift*, No. 47, 1887), has found that antifebrin exerts an extremely prompt action in hemicrania, even in obstinate and old cases. He gives seven and one-half grains at the beginning of the attack. The result is said to be admirable. The drug also did good service in a woman suffering from trigeminal and occipital neuralgia, with dysmenorrhœa.

Human Electricity.

A hemi-anæsthetic, hysterical woman, says the *Lancet*, February 11, 1888, was shown at a recent meeting of the Société de Biologie, from whom M. Féré could, under certain circumstances, disengage at the surface of the body luminous tufts, one-sixth of an inch long. The son of this woman, likewise hysterical, presented the same peculiarity. In both the skin was remarkably dry. These phenomena could be easily augmented by provoking sensorial excitations. Such phenomena are known more commonly in certain hot and dry tropical climates.

Injections of Quinine in Gonorrhœa and Cystitis.

Dr. Frank L. James says that after reading in the *Indian Medical Gazette*, a number of years ago, a clinical note by a native surgeon in the British East Indian Service on injections of quinine in the early treatment of gonorrhœa, he tried the formula there recommended. He found it extremely painful, the quinine being dissolved in an acid mixture. He then tried the following formula:

℞ Quininæ sulphatis.....ʒss
Morphinæ sulphatis.....gr. viii
Mucilaginis acaciæ.....fʒiss
Aquæ q. s. ad.....fʒviii
M. Fiat mistura.

He found this "cooling and soothing" when injected into the urethra in quantities of half an ounce. The first patient upon whom it was tried got well with great rapidity. Since that time he has used the remedy many hundred times and while sometimes duplicating his first success, and sometimes failing utterly with it, he says that in about sixty (60) per cent. of all the cases in which it was faithfully used in the earlier stages of the disease, it brought about a rapid and almost painless recovery. Subsequent experience has taught him that when used in the latter stages it was rarely of any service.

He also states that the results of intravesical injections by gravity have been very gratifying both in acute and chronic cystitis, in old gleets and even in prostatic troubles.

In the treatment of acute blenorrhœas with the quinine mixture, he usually advises the patient to inject a half syringeful before urinating, and if there be much ardor urinæ to immerse the parts in water as hot as he can bear it; to urinate in the hot water, and after urination again to inject the quinine mixture. For chordee he says he finds nothing to equal veratrum viride, twenty minims of the tincture to be taken on retiring.—*St. Louis Med. and Surg. Journal*, April, 1888.

Paraldehyde Mixture.

Schmitt recommends (*Rundschau, Prag.*) the following very expeditious way of making a mixture of this substance: 20 parts of paraldehyde are vigorously shaken in a bottle with 30 parts of syrup and 60 parts of mucilage, and then at once 90 parts of water are added, shaking again. If the quantity of water does not greatly exceed 90 parts, the paraldehyde will remain suspended.—*Druggists Circular*, April, 1888.

Creasote in Phthisis.

Dr. Peter Kaatzer, of Rehburg, strongly recommends, in the *Berliner klinische Wochenschrift*, March 12, 1888, the administration of creasote in the treatment of phthisis. After trying various formulæ he has settled upon the following as the best:

℞ Creasoti purissimi.....2 parts
Alcoholis.....30 "
Tr. gentianæ,
Ext. caffeæ.....āā..10 "
Aquæ destillatæ.....100"
M. Sig.—Shake well and take a tablespoonful in half a glass of milk twice daily.

Cocaine in Dilatation of the Cervix for Dismenorrhœa.

Dr. M. F. Birdsong, in a communication to *Daniel's Texas Medical Journal*, March, 1888, says that in a young married woman, 20 years old, who had menstruated first when

13 years old, he had occasion to dilate the cervix for painful menstruation. The cervix was long and slender, with pinhole os; nothing else abnormal was discovered. As she was opposed to taking chloroform, he proposed to use cocaine as a substitute, to which she consented. He used the following solution:

Cocaine hydrochlorate.....gr. x.
Water.....m x.
Liquid vaseline.....f ʒ iv.
M.

Two slender whale-bone probangs were wrapped with absorbent cotton, and the cotton saturated with the solution. One of them was introduced fully into the uterus and left *in situ*. Absorbent cotton was saturated with the solution and packed around the vaginal portion of the cervix and allowed to remain for fifteen minutes, when it was all removed and another application, as above, was used, and allowed to remain the same time, when it also was removed. The dilator was then introduced and dilatation began at once, and in a few seconds it was over. For fear he had not fully dilated the internal os, he closed the instrument and pressed it in farther, and dilated again. All of this was done with but little pain to the patient. In about ten days she menstruated with but little pain, not more than is common for women, and is now pregnant and in fine health. A second case, in which lanoline was used for vaseline, with equally successful result, is also mentioned.

For Burns.

The following formula, says the *Deutsche med. Wochenschrift*, March 15, 1888, is recommended by Nicot, Vuillet, and other French authors:

Salol.....grs. 37½
Lime water,
Olive oil, of each.....drachms 2⅓
Mix. Use as an ointment to the affected parts.

Irido-Choroiditis from Exposure to Sunlight.

It appears that Professor Plateau, of the University of Ghent, while trying to observe the effects of the irritation of the retina gazed steadily at the sun for twenty seconds, the result being that chronic irido-choroiditis developed, ending eventually in total blindness. A number of cases are known in which choroiditis and retinitis occurred in persons who had observed an eclipse of the sun. The single flash of a sun reflector has been known to cause retinitis, and other temporary visual disturbances of a functional character have been frequently noted.—*Public Opinion*, March 24, 1888.

Water from the Sea for English Towns.

The scarcity of water in many large towns in Great Britain is causing much alarm. The city of Liverpool, and the sister city, Manchester, are in great danger of a water famine, the former having only about ten days' supply in the reservoirs. A proposal to bring sea water in mains from the coast to the large inland towns of England has been made by Mr. Ellis Lever, of Manchester, and has been received with much favor by the press and public. Mr. Lever's proposition is to lay pipes for sea water, side by side with the fresh-water supply, and that the sea water should be used for baths, closets, watering streets, flushing sewers, and in extinguishing fires. For all this, and many other purposes, sea water is more efficient than fresh water. The object Mr. Lever has in view is to economize the fresh-water supply. The question is forcing itself upon the attention of the British Parliament, and a proposal is being made to appoint a royal commission to inquire into the water-supply of Great Britain. The King of the Belgians is also alive to the importance of this subject, and has offered a prize of 25,000 francs for the best treatise on the water-supply of large towns.—*N. Y. Evening Post*, April 4, 1888.

Appointments at St. Agnes's Hospital.

The new Hospital of St. Agnes in Philadelphia, is to be formally dedicated during the latter part of the present month, and patients will be received early in May.

The following is the staff of physicians and surgeons:

Medical Director, Dr. J. H. Grove, A.M., M.D., LL.D.

Medical Staff, Professor Horatio C. Wood, M.D., LL.D.; Professor James Tyson, Dr. John M. Keating and Dr. Michael O'Hara.

Surgical Staff, Professor W. W. Keen, Professor J. Ewing Mears, Professor John B. Roberts and Dr. Joseph M. Fox.

Medical Out - patient Department, Dr. George Dock and Dr. Hobart A. Hare.

Surgical Out-patient Department, Dr. J. F. Walsh and Dr. Charles B. Penrose.

Ophthalmologists, Dr. Charles A. Oliver and Dr. Francis M. Perkins.

Dispensary for Throat, Nose and Ear, Dr George Y. McCracken and Dr. John Sheets

Gynecologist, Dr. D. W. Cadwallader.

Dispensary for Diseases of Children, Dr. Robert Kilduff.

Pathologist, Dr. Andrew J. Downs.

Jefferson Medical College Prizes.

At the sixty-third annual commencement of the Jefferson Medical College of Philadelphia, April 4, 1888, prizes were awarded as follows:

1. A prize of $100 by the *Medical News*, for the best Thesis, to Laurence Reynold Ryan, of Illinois, with honorable mention of the thesis of George M. Gould, of Massachusetts.

2. A gold medal, for the best essay on a subject pertaining to the practice of medicine, to Augustus A. Eshner, of Pennsylvania, with honorable mention of the essays of William Louis Baum, of Illinois, and William L. Whittington, of Missouri.

3. A gold medal, for the best anatomical preparation, to William M. Browder, of Alabama, with honorable mention of the preparation of John W. Groff, of Pennsylvania.

4. A gold medal, for the best work in chemical laboratory, to John Charles Hierholzer, of Pennsylvania.

5. A case of instruments, for the best original research in the Materia Medica Laboratory, to Jacob S. Pragheimer, of Pennsylvania, with honorable mention of the essay of Samuel Tevis, of California.

6. A gold medal, for the best essay on a subject pertaining to physiology, to John J. McFadden, of Pennsylvania.

7. A case of instruments, for the best essay on a subject pertaining to surgery, to Edward L. Beal, of Missouri.

8. A gold medal, for the best essay on a subject pertaining to obstetrics, to Sylvester S. Kring, of Pennsylvania, with honorable mention of the essay of J. Howard Frick, of Pennsylvania.

9. A case of instruments, for the best essay on a pathological subject, to Edgar Parker Hershey, of Pennsylvania.

10. A gold medal to William Stephen McDonald, of Maine, for the best report of Dr. Thomas G. Morton's Surgical Clinic at the Pennsylvania Hospital.

Correction.

Prof. Gross says that the class-room note on the "Preservation of Ligatures," (REPORTER, March 10, p. 318), taken from the *College and Clinical Record*, should have been "Preservation of *Sutures*," the formula being Macewen's. He also says there should be no carbolic acid in the solution used to preserve them (alcohol, parts 15, glycerine, part 1).

NEWS.

—Dr. Martineau, the well-known physician of Paris, died recently at the age of 52 years.

—It is announced that Dr. Oliver Wendell Holmes has given his medical books to the Boston Medical Library.

—The death of Dr. Hippolyte Blot, Secretary of the French General Association of Physicians, is announced.

—The Missouri Medical College held its annual commencement March 6. The school is in a prosperous condition.

—Dr. Robert Travers, Professor of Medical Jurisprudence in the University of Dublin, died March 27. He was appointed Professor in 1864.

—It is customary in the election of a President of the Royal College of Physicians of England to give, after the election, to each Fellow present, a new half-crown. The origin of the custom is not known.

—The Philadelphia College of Pharmacy at its 67th annual commencement held recently graduated 137 as pharmacists, including one young lady. This is the largest class the school has ever graduated.

—An Indiana doctor is said to have begun marrying in 1832, and now at the age of seventy-five to have just married his seventh wife. None of the seven was over thirty-one years old when she became the doctor's wife.

—The *Ledger*, March 16, 1888, says: A real live British peer in America is John Contee Fairfax, M. D., of Northampton, Maryland. According to "Debrett's Peerage" he is the eleventh Baron Fairfax, and last year he received from the Queen a formal invitation to be present with his fellow-peers at her Jubilee in Westminster Abbey. This invitation he did not accept. He has now retired from the active practice of his profession, and lives a quiet, simple life on his farm. The dowager Baroness Fairfax, widow of the tenth Baron, is living on a ranch in California. Numerous uncles, aunts, and cousins of Lord Fairfax are living in this country. Many of them took part in the Rebellion, but one of them became a Commodore in the United States Navy. It was Thomas, the sixth Baron Fairfax, who settled the family in this country. They are all descended from the famous Fernandino, second Baron, who led the revolutionary forces and defeated the King at Marston Moor; and from his son Thomas, third Baron, who commanded the cavalry at Marston Moor and was in chief command at Naseby.

HUMOR.

In the chemical laboratory: Professor —What has become of Tom Appleton? Wasn't he studying with the class last year?"

"Ah, yes; Appleton—poor fellow! A fine student, but absent-minded in the use of chemicals—very. That discoloration on the ceiling. Notice it?"

"Yes."

"That's Appleton."—*Tid-Bits.*

A young preacher the other day, undertaking to "stump" Bishop Foss, of the Methodist Church, with a "temperance" question, said: "Why, brother, if there was a mad dog running up and down the streets, would you shoot it or would you hedge it in?" To which the wise bishop made quick reply: "If that mad dog had been running up and down the streets for 30 years, and I had been blazing away at it all that time without hitting it, I guess I'd try and hedge it in."—*Chicago Advance.*

"That farm scene you seem to be sneering at, sir," said the indignant artist, "is valued at $500. It is generally considered a fine painting. Allow me to ask you if you are familiar with works of art?" "Not very familiar," replied the agriculturist, who was looking through the studio with his wife, "but I know something about the works of nature, young man; and when you make a cow that gets up from the ground by putting out her fore feet first you are doing something that nature never did."

The Secretary of the Health Department of Baltimore receives many curious certificates from physicians of that city. From a number recently sent in the following "causes of death" are worthy of note: A report on the death of a lady, eighty-five years of age, reads: "Cause of death, fall from third-story window. Seeing it was a fatal case I let her die in peace, which she did in one hour and twenty minutes." Another certificate makes the sad announcement: "A boy four years old died from eating a heavy piece of apple-pie four hours before death."

An English Gentleman found a large turnip in his field of the shape of a man's head, and with the resemblance of the features of a man. Struck with curiosity, he had a cast made of it, and sent the cast to a phrenologist, stating that it was taken from the head of a celebrated professor, and requested an opinion thereon. After sitting in judgment, it was reported that it denoted a man of acute mind and deep research, that he had the organ of quick perception, and also of perseverance, with another that indicated credulity.—*Kansas City Med. Record*, March, 1888.

Sausages, cooked or half raw, highly spiced, are an essential of German cookery. In order to prevent the Germans from exposing themselves to a number of bad diseases incidental to pork, the authorities insist upon the pigs being examined before being offered for sale. A peasant was arrested for evading this law, and upon being asked to to explain, said that he had a most accurate method of determining the soundness of pork. The pastor of the district was always hungry, so the peasant always sent him the first sausage made from each pig slaughtered, and a week later called to inquire after his health. If it was all right the pork went to market, and the examination fees were saved.

OBITUARIES.

S. C. THORNTON, M.D.

Dr. S. C. Thornton, died recently at his home in Moorestown, New Jersey. He was graduated from the University of Pennsylvania in 1852. His funeral on April 13, was attended by a number of the members of the Burlington County Medical Society.

Official list of changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from April 8, 1888, to April 14, 1888:

Capt. Geo. E. Bushnell, Assistant Surgeon, from Fort Preble, Me., to Camp Pilot Butte, Wyo.

First Lieutenant Wm. Stevenson, Assistant Surgeon, from Camp Pilot Butte, Wyo., to Fort Verde, Ariz.

First Lieutenant E. A. Mearns, Assistant Surgeon, from Fort Verde, Ariz., to Fort Snelling, Minn.

First Lieutenant Wm. L. Knudler, Assistant Surgeon, from Fort Snelling, Minn., to West Point, N. Y.

First Lieutenant W. C. Border, Assistant Surgeon, from Fort Douglas, U. T., to San Antonio, Tex.

First Lieutenant G. L. Edie, Assistant Surgeon, from San Antonio, Tex., to Fort Douglas, U. T. S. O. 79, A. G. O., April 6, 1888.

Changes in the Medical Corps of the U. S. Navy for the week ending April 14, 1888:

Passed Assistant Surgeon Henry T. Percy, from Naval Academy, and to Hospital, Washington, D. C.

Passed Assistant Surgeon M. H. Crawford, from Hospital, Washington, D. C., and wait orders.

Surgeon J. M. Flint, from Fish Commission duty, and special duty at Smithsonian Institution.

Surgeon R. C. Persons, to duty in charge of Army and Navy Hospital, Hot Springs, Ark.

Assistant Surgeon E. P. Stone, from further treatment, and to duty, Hospital, New York.

Medical Director David Kindleberger, from Hospital, Washington, D. C., and wait orders.

Medical Inspector A. A. Hoehling, to Naval Hospital, Washington, D. C.

Passed Assistant Surgeon G. E. H. Havmon, to duty Naval Academy, Annapolis, Md.

Clinical Lecture.

PARALYSIS AGITANS; LOCOMOTOR ATAXIA; LATERAL SCLEROSIS; PARAPLEGIA.

BY DANIEL R. BROWER, M.D.,

PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM, DIDACTIC AND CLINICAL, WOMAN'S MEDICAL COLLEGE; LECTURER ON THE PRACTICE OF MEDICINE, RUSH MEDICAL COLLEGE, CHICAGO.

(Reported by William Whitford.)

Paralysis Agitans.

The patient to whom I first direct your attention is 73 years old. She has had this fine rhythmical tremor which you observe about four years. She tells us that it first began in the feet, then it made its appearance in the fingers of the left hand, and later manifested itself in the right side. This kind of tremor we call *paralysis agitans*. It closely resembles the tremor of multiple sclerosis, but you notice that it is a fine, constant, rhythmical movement, uncontrollable by the will power. Now, let us see if voluntary movement increases it or not. Sometimes in this disease it does, sometimes it does not. In this case it does not; it works with the utmost regularity—in fact as regularly as the movements of the pendulum of a clock. It is present when there is no effort at voluntary movement. The tremor of multiple sclerosis is coarser, more jerky, as it were, and it is not present, in the early history of the case, unless the patient attempts voluntary movement. The tremor of paralysis agitans, however, is present only when patients are awake; when they are asleep it ceases. The unusual feature about this case is, that the tremor began in the lower extremities. Usually it begins in one of the upper extremities, in the index finger and thumb, making what has been called the "pill movement," after which other fingers or areas of the body become involved—an arm, for instance; then it may jump to the other side, and finally reaches the lower extremities. You notice, also, in this case the tremor about the head.

The gait of paralysis agitans is peculiar. You notice the position of the body; the head is well in advance of it, during locomotion; she tumbles forward when she gets up to walk. As Trousseau says, these patients seem always to be pursuing their centre of gravity.

The pathology of paralysis agitans is shrouded in mystery. In some recent cases chronic degeneration has been found around the central canal, and in the column of Clarke of the spinal cord; also, in the cerebellum in the corpus striatum, and in the cerebral cortex.

It is a disease of old age, but every now and then it shows itself in young people. I saw a patient not long ago only thirty years of age, in whom the tremor had been manifested for three or four years. I have seen other cases under forty; but, as a rule, it is a disease which occurs in people of sixty-nine to seventy years of age.

Treatment.—Whatever the pathology of the affection may be, it is due to a depressed condition of the nervous system, and it demands for the prevention of its rapid progress judicious tonic treatment. The tremor, which is the most disagreeable feature of the disease, is controllable to a very large extent by the administration of hyoscyamus, or its alkaloid hyoscyamine. We will order for this patient one sixtieth of a grain of hyoscyamine at bedtime, and a capsule containing one-tenth of a grain of phosphide of zinc after eating, three times a day.

The subcutaneous injection of arsenic is sometimes of much service. You can take the tablets of arseniate of sodium, one-tenth

of a grain each, and give one injection daily. The ordinary Fowler's solution is very liable to produce abscess if used subcutaneously.

Do as you may you cannot cure the disease, but you may alleviate it.

Locomotor Ataxia.

Observe the peculiar locomotion of this patient; see to what extent he widens his base as he walks. You notice that he brings his heels down first; the back part of the heels of both shoes are considerably worn. He is forty-nine years of age, and was attacked with this disease four years ago. He has sensations of pins and needles, running from the elbow down to the tips of his fingers. I am pricking him severely, you notice, with a sharp-pointed pin, and he does not feel it. The tactile sense has disappeared, and there is but little appreciation of pain sense in the left hand. There is comparatively little tactile sense in the right hand; pain sense is also slight. A severe prick with a pin is slightly appreciated. He says he has darting pains all over his body; they come suddenly and disappear suddenly. Three or four days ago he said he had pain in the left foot, in a spot about half an inch square. The pains are localized, they do not follow the course of the nerve trunks. They do not often occur twice in the same place; they do not include the whole limb; a half dollar will usually cover the point of this sharp, shooting pain. Notice his eyes; they do not respond to light, and the pupils are contracted.

We will now see what the condition of the patellar-tendon reflex is. We will have him clasp his hands and attempt to pull them apart, and in this way we will do two things: (1) Increase the muscular tonus; and, (2), Divert his attention, and if there is any reflex we will find it out by tapping just below the patella. There is no response in the left nor in the right leg. It is not the absence, simply of patellar-tendon reflex that is pathological, because we now and then meet with perfectly healthy people who have no reflex, but it is the loss of it. If it was present, and is absent now, we know there is some pathological disturbance.

A physician of this city found out a few years ago that he had no patellar-tendon reflex. He therefore studied his spinal condition, and began to wonder if he had incipient locomotor ataxia. He became much alarmed about himself, and began investigating the question of patellar-tendon reflex, and it is surprising how many persons he has found in perfect health who have no such reflex. So the simple absence of it is not necessarily pathological.

Let us test his power of coördination. I will make a little spot on his forehead, and ask him to touch it with his finger. You see he does not come within three-fourths of an inch of hitting it. I will now have him stand erect with his feet close together and his eyes shut. You see he would fall if I did not support him. The loss of patellar-tendon reflex, the incoördination of muscular movement, the peculiar locomotion, makes this a case of locomotor ataxia. The numbness, the loss of tactile sense, the incoördination of muscular movement, began in the left upper extremity. The disease usually begins in the lower extremity.

He had this disease about a year before he came to Chicago. He came from the West, and while there his pains were not very severe. Neither had he any trouble with the lower extremities. The disease must have invaded the lumbar enlargement of the spinal cord when he came to this city. He tells us that he had a sensation as though he was walking on carpet or wool when he first came to Chicago.

Case II.—We will next turn our attention to the patient sitting along side of him. He is fifty-eight years of age. A year and a half ago he began having pain in the feet and in the legs, and has it now. He describes it as "sharp, shooting, and lancinating" in its character, which quickly disappears and returns, the interval between the attacks being about a minute and a half. He has this pain about once every two weeks. We will ask him to walk across the room. You notice that the gait is of the same character as in the patient who has just been examined; there is some broadening of the base as in the other case; he brings down his heels first, and the heels of his shoes are worn in the same manner. Patellar-tendon reflex is gone. I will now make a little spot with a pencil on his forehead, as we did in the other case, and ask him to touch it with the tip of his finger. You see he cannot do it. His pains commenced first in the arms, then attacked the shoulders, and then the fingers. There is loss of pain sense; tactile sense is not lost to such an extent as in the other case, but it is impaired. He distinguishes between tactile and pain sense. His pupils are contracted.

We will now ascertain the conditions of the color sense of these two patients. We have here four blocks of four different colors. In some cases of locomotor ataxia a very important symptom is the loss of color-sense,

red and green being lost first. Color-sense in these two patients is good. The first patient has a sensation of something tight around the body as a rope or band, the so-called "band sensation." Occasionally in the history of the disease, one of the most disagreeable and uncontrollable symptoms is what is called the "gastric crisis," that is continuous vomiting with pain. The pain is like that experienced in other parts of the body; it appears and then suddenly disappears. So the nausea without the slightest provocation will sometimes appear and abruptly stop.

Treatment.—In the early history of these cases, before the ataxia is manifest, when you can recognize by certain symptoms the beginning of the disease; when, in other words, you have an impairment of the reflexes, disturbance of color-sense, dysæsthesias throughout the body, impairment of tactile and pain sense, mental depression and irritability of disposition, severe localized pain—you may do something for the relief of your patient and sometimes cure him. If you treat the disease vigorously in the pre-ataxic stage, you can every now and then arrest it. You do this by putting the spinal cord as near as possible in a state of absolute rest. Put your patient to bed, keep him in the horizontal position; by judicious massage and Faradic exercise of the muscles prevent the possibility of their wasting; give him, at the same time, such internal treatment as is indicated and in accordance with the etiology of the case. If you are satisfied the case is specific, give anti-specific remedies, and the best is perhaps Donovan's solution—liquor arsenici et hydrargyri iodidi. If there is no specific history the treatment should consist of nitrate of silver, in doses of one-third of a grain, rubbed up with cosmoline to prevent decomposition, and given before eating three times a day. This can be continued two months without any danger of producing discoloration of the skin; then after an interval of two months another course may be given with safety and sometimes with benefit. Phosphide of zinc will sometimes benefit these cases.

The constant galvanic current to the spine and the Faradic brush to the body is also generally of service. The actual cautery to the back will occasionally relieve the pains and probably delay the progress of the disease.

Lateral Sclerosis.

Please notice the difference in the locomotion of this patient as compared with the other two who just appeared before us. He walks without any special effort of widening his base or disposition to bring the heels down first. He is 34 years of age, and says he had typhoid fever and inflammation of the liver some three or four months ago. He says his limbs are not as strong as they were. They feel stiff, and the muscles are rigid. He gets tired easily in walking; they, the limbs, feel heavy and are moved with difficulty. We test the patellar-tendon reflex as before, and find it much exaggerated in both limbs; we examine the limb for ankle clonus by flexing the foot suddenly upon the leg, and you see that it has set up a rhythmical tremor. We will have him, while in the sitting posture, work his leg up and down upon the foot. Having started the movement, you notice he cannot stop by a simple exercise of the will; consequently we have in this case a loss of power of the lower extremities, the exaggeration of patellar-tendon reflex, and the ankle clonus. There is no impairment of tactile sense, and no impairment of pain sense. The weakness and stiffness of the lower extremities, the exaggeration of the reflexes, and the ankle clonus, the absence of any particular sensory disturbance, pain or touch sense, make this case one of *lateral sclerosis*.

The treatment of this disease is practically the same as for locomotor ataxia.

Case of Paraplegia.

We have one more case to which we ask your attention. The patient is forty-five years of age. Fifteen months ago he was perfectly well. He tells us he was driving in a very exciting race; and when it was over and he tried to get out of the sulky, he found he had loss of power of the lower limbs. He had at the time of the seizure acute pain in the back, and for about a year numbness of both legs. There was also paralysis of bladder and rectum, for some weeks after the seizure.

His legs, you notice, are very much wasted, and that the paralysis is complete. Sensation is diminished, but he says that it is improving.

Spinal Apoplexy.

The atrophy of the limbs suggests anterior acute poliomyelitis. We differentiate by the instantaneous onset, the sensory disturbance, and the involvement of bladder and rectum.

As to the treatment of paraplegia, something can possibly be done in the way of restoring muscular power to the lower extremities by the use of massage and electricity. Electricity and massage offer the only possible chance of benefit to such patients. If the limbs respond to an interrupted galvanic cur-

rent; if you can make the muscles contract by such a current, then you can improve nutrition and benefit patients. But if you cannot apply the current in sufficient strength to produce muscular contraction, there is no advantage whatever in using electricity, nor hope of restoring function. Iodide of potassium and general tonics may be administered.

RUPTURE OF THE PERINEUM. PELVIC PERITONITIS

BY WILLIAM GOODELL, M.D.,

CLINICAL PROFESSOR OF GYNECOLOGY IN THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

The first case I have to show you this morning is one of perineal rupture, and I shall repair the injury before you. It is not what is usually termed a bad case; that is, the tear does not extend into the rectum. The large majority of these cases do not involve the whole of the sphincter ani. You should try not to allow such extensive tears to occur in your practice; but you will not always succeed. Yet you will generally escape having bad tears if you, as a rule, will remove your forceps as soon as you have brought the presenting part so low down as to distend the perineum. Most of the serious tears are occasioned by the traction on the forceps when the perineum is the only remaining obstacle to delivery. All these ruptures should be sewn up immediately upon the completion of labor. I can hardly imagine an exception to this rule. If they are slight, a few words of explanation to the woman will remove any objections she may have, and a few stitches will quickly repair the damage with but little pain. If they should be more extensive, ether may be administered and a skilled assistant should be present. The condition of this perineum, which we now have to operate upon, does not seem to be as bad as it really is. The tear originally extended to the sphincter, but a certain amount of spontaneous healing has taken place, and we now have to deal with the following conditions: The hard, unyielding cicatricial tissue which has developed at the site of the wound, acts as a splint and keeps the entrance to the vagina open. Air enters and escapes from the canal with every movement. Its floor having been destroyed, prolapse of the anterior vaginal wall has occurred; and, in time, the posterior wall will follow, dragging the womb down with it. Even now she suffers from the bearing down sensations which constitute the chief source of complaint coming from these cases.

Previously to beginning the operation, the parts involved are freed from hair, since this is not only in the way during the operation, but it may get between the edges of the wound and interfere with or prevent union. Having determined where the upper margin of the perineum should be by bringing the edges of the cicatrix together, we are ready to proceed with our work. You will find that the perineum is probably the most sensitive portion of the body. It has an abundant nerve supply and you can see now, that although this woman is thoroughly under the influence of ether, yet she winces as the knife enters the tissues. It becomes even more sensitive than usual when, as is the case here, a mass of dense cicatricial tissue is present. I begin by dissecting off on one side a small horse-shoe shaped piece of the cicatrix, and then, passing my finger into the bowel to prevent cutting into it with my knife, I dissect up a flap, or pouch, of vaginal mucous membrane, which you can see projecting into the wound. Having done this, I trim the edges of the whole wound, and make the outlines of each side as like as possible. Now I am ready to sponge off the bleeding surfaces and insert the sutures. I have tried almost all of the many operations that have been devised for ruptured perineum, and I must confess that this one receives my preference. By it a thicker and stronger perineum is obtained than by any other. I save all the tissue that can be of any use in increasing the bulk of the perineal body and adding strength to its floor. I have removed, as you have seen, only one little horse shoe of the cicatrix and have utilized all the rest. I have simply dissected up one large flap from the hind wall of the vagina and from the sides of the vulva, and the raw surfaces are now ready to be brought into apposition. This operation not only procures a thick floor for the perineum, but it has the additional advantage of not having any cicatrix inside of the vagina. I have never failed to gain perfect union. Some time since, I performed this operation upon a patient from New York. Several months afterwards she became pregnant and I recommended her to the care of a friend of mine in that city. This gentleman, writing to me subsequent to her confinement, and referring to the new perineum which I had made for her, said that "the only fault he had to find with my operation was, that the perineum was *too good*." In other words, the labor had been delayed when the presenting part of the child had reached this point,

and it was only after several slight lateral incisions had been made, that the perineum yielded sufficiently to permit the child to be born.

For sutures in these cases I use the thinnest possible wire compatible with safety. In this woman, who is rather spare, I shall use No. 29; in fat women I use No. 27. My first two sutures are buried deep in the body of the perineum and do not show in the wound at all. The upper sutures, on emerging from the left side of the vulva, in which they are first inserted, are passed through and buried in the vaginal flap before they enter the opposite side of the vulva. Now that they have all been inserted, you can see that even before they have been drawn taut, I have thus gained a back wall to my perineum. The sutures may be left in certainly for a week, and I don't object at all to ten days, particularly in those cases where some degree of tension is needed in order to bring the denuded surfaces together. I have used six sutures here and you notice that they occasion some little tension. Where the wire is fine, however, this need cause you no uneasiness; for, should the wire cut, the tissues heal behind it as rapidly as they are severed. Now, we dust the wound with iodoform and the operation is concluded.

Do not syringe out the vagina! I have two reasons for giving you this piece of advice. The first one is, that in order to use your syringe you must lift the patient upon a bedpan, and the traction upon the perineal muscles to which this movement gives rise tends to separate the edges of the wound. My second objection is, that the nozzle of the syringe is very liable to interfere with the union at the upper stitch. In the after-treatment of these cases, I endeavor to get along with as little opium as possible. Its use as a routine measure is, I have come to believe, deleterious; and, therefore, I administer it now only when it is really necessary, and then only in just sufficient amount to secure its desired effect.

Secondary hemorrhage after this operation is of exceedingly rare occurrence. In all of my own experience I have had it happen but twice. The first of these cases was that of a woman upon whom I had operated in the afternoon, and to whom I was called early the next morning. I found a pretty free hemorrhage in progress, but it was easily and quickly controlled by the pressure of a sponge which was introduced just within the entrance of the vagina. The flow of blood probably proceded from some vessel which had not been included in the sutures. The second case was one almost precisely similar to this, and the hemorrhage was checked in the same simple way. The pressure exerted by the sutures is nearly always sufficient to prevent any bleeding, and, when it is not, the use of a sponge in the above manner will be found all that is necessary. The sponge stops the hemorrhage by pressing firmly upon the mucous flap which forms the back wall of the new perineum.

Pelvic Peritonitis.

Widow, 25 years old. Has one child. Husband has been dead five years. She has just been admitted, and no one has examined her, but she states that her physician calls her disease *acute peritonitis*. Let us see. Her pulse is 120, but, gentlemen, its acceleration is due to nervousness; it is a pulse indicative of fear—not fever. With the exception of this rapidity, it has none of the characteristics of the peritonitis pulse. Her tongue, also, is totally unlike that which usually accompanies this disease. The tongue of peritonitis is denuded in the centre, it is red and raw, never coated, but unnaturally clean and dry. Now, I shall examine the patient, and, I find, that she indeed *has* peritonitis, but it is not general nor is it acute. It is, on the contrary, localized and subacute. I detect on either side of the cervix a dense mass of tissue which feels like so much tallow. Pressure gives her acute pain, and I conclude that we have here the fruits of a circumscribed peri-uterine inflammation, a pelvic peritonitis. (Patient removed.)

What has caused it? Well, this is hard to say; but, a very common cause of this malady in the lower classes is gonorrhœa. Just before she was taken out, I asked her in a whisper if she ever had this disease, but she denied it. Such denials, however, are to be received with a good deal of caution, and particularly in this class of patients which feeds our clinic. Still, to give her the benefit of the doubt, such a complication may result from a cold caught while menstruating, from attempts to induce abortion, from the introduction of an unclean sound, or from other causes wholly innocent in character. There is one good feature about the virus of gonorrhœa and the pelvic inflammation to which it gives rise, and that is that it is almost always superficial in its action and that it does not penetrate deeply beneath the surface and end in troublesome abscesses. Peritonitis occurring as the result of other causes frequently ends in an abscess, which is liable to point and rupture into the rectum or vagina. Yet, often, all traces of the pelvic inflamma-

tion will vanish and the woman may again be restored to perfect health. Not so, however, with the products of gonorrhœal inflammation, which rarely form abscesses; although pus may be found in the tubes and ovaries. Very firm adhesions are the usual outcome of this variety of peritoneal inflammation, and, in this peculiarity, I think, we may find an explanation of the well-known fact that prostitutes are commonly sterile. Almost all of them at one time or other have had attacks of gonorrhœa which are accompanied by localized peritonitis. This may be very slight; perhaps, indeed, the woman may not be conscious of her additional trouble, but it will leave its traces in displaced ovaries, adherent tubes, flexions of the uterus, etc., and it is these which interfere with conception.

COMMUNICATIONS.

FIRST IMPRESSIONS OF UNDEVELOPED DISEASES, AND FIRST TREATMENT.

BY ENOS T. BLACKWELL, M.D.,
CEDARVILLE, N. J.

There is no truth more potent to the observing physician than that many ailments present themselves to him primarily in such an imperfect form as to task his diagnostic powers to the utmost; and, that at times, his keenest erudition leaves him still in doubt to what nosological class he shall assign the specimen before him.

The careful physician will, therefore, be wary how he enters upon the treatment of obscure cases, lest, while endeavoring to cure, he really injure his patient's chances of recovery. Much depends, therefore, on the physician's first view of cases of this character; and his success must largely depend on his ability to read aright the scanty indications that are furnished him.

There is no disease, perhaps, which is more apt to mislead the practitioner in this regard than typhoid fever. Sometimes it presents itself as an open specimen of malarial fever, with its typical phenomena of paroxysm and recession. There may be nothing in the appearance of the skin, the tongue or in the facial expression that suggests a dangerous affection. There may be sluggishness, or even constipation of the bowels. Should there be some evident disturbance of the liver and stomach, with dark color of the skin, he may be quite confident in a diagnosis of paludal fever, and govern himself accordingly. If he proceed to use medicines adapted to the fever alone, and leave the apparent secretory trouble for further observation, without attempting to combat it by active cathartics, I think he will not regret it.

Should he prescribe some mild laxative, no damage may be done, or even positive benefit ensue; but, should he give active purges, with a view of arousing the emunctories, he may have most violent catharsis and consequent injury, if his disease should prove to be enteric in character. The affection of the glands of Peyer may have been so moderate as to have caused neither diarrhœa, nor suspicion of disease there; but, an active cathartic having been exhibited—especially if it be of a resinoid nature—there is developed a most painful and harmful diarrhœa.

In reviewing my own experience in typhoid fever—an experience generally of success—I recall two cases in which from insufficient knowledge, I gave an active cathartic—calomel and podophyllin—with the idea of loosing the emunctories beneficially; but, unfortunately, with injury to the patient. One of them was a young medical student returning in spring from close attention to medical lectures, and from fearless investigation among the fever-stricken patients of Bellevue Hospital. He was listless and unable to study, and his skin had a decidedly darkened color, which was attributed to biliousness. He proposed to "work off" his indisposition in the garden; and to assist in this laudable undertaking, received a full dose of podophyllin and calomel. The result was hypercatharsis, and great reduction of strength. His disease proved, when fully formed, a most violent infectious fever, of which he died. A like result occurred in the other case, which also proved fatal.

It will be well, then, for the physician, who has a patient too ill to labor, and disinclined to take to his bed, especially if this condition has existed for several days, to be careful in the exhibition of active purges with a view of clearing the intestines and unlocking the secretions, even if indications seem to suggest them. There is much difference of opinion, too, as to what constitutes a mild aperient suitable for an initial disease. That castor-oil, when given in full dose causes paroxysms of pain, when the expulsive throes come on, no one can doubt who has ever taken the medicine. A suitable remedy, taken in small and often repeated doses, will open the bowels with less irritation and distress than a larger portion exhibited at longer intervals. It is doubtful whether any medicine will give better results than calomel, in

grain or half-grain doses, repeated every two hours until an evacuation take place. By this means the bowels are gently persuaded, and not violently coerced with consequent irritation and distress.

If, therefore, in making acquaintance with a recently presented specimen of disease, we study its demeanor and characteristics, waiting patiently the unfolding of its true nature, we may gradually come to know its quality, and settle deliberately to a sensible and rational treatment. We shall thereby avoid any charge of rashness in any opinion we may give, or any treatment we may institute; and be guiltless of unsuccessful practice founded on insufficient investigation. Our patient, also, will derive the benefit that is to accrue to him from the services of a self-poised and scientific dispenser of the healing art, instead of one who daily changes his opinion of the nature of the distemper under observation, and the treatment suitable for its cure.

DEATH FROM EARLY SEPTICÆMIA FOLLOWING A PUNCTURED WOUND OF THE TOE BY A SPLINTER—A LESSON IN SEPTIC SURGERY.[1]

BY W. W. KEEN, M.D.,

PROFESSOR OF SURGERY IN THE WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA; SURGEON TO ST. MARY'S, ST. AGNES'S AND THE WOMAN'S HOSPITALS, ETC.

I. T., aged 26, a steel engraver. While walking across his floor at 8 P.M. on Thursday, February 9, 1888, a hemlock splinter pierced his shoe and punctured his left great toe on the inner side opposite the phalangeal articulation. He did not return home until 11 P.M., as his foot did not hurt him badly. A doctor was then called who thought he removed the entire splinter. Eight days later, however, another piece, one inch long, which had remained undiscovered was discharged spontaneously. The wound was dressed with lead water and laudanum, with some carbolic acid.

February 10. Dr. Bartleson, his regular physician, saw him the next morning, found the toe slightly inflamed, but not tender, and the splinter presumably removed. The only symptom was a severe pain extending up the leg as far as the hip, which was quieted by a moderate dose of morphia.

On the morning of the 11th, and therefore only thirty-six hours after the original injury, his temperature ran up to 104.5° F., with great pain in the left-shoulder joint. For several days his temperature ranged from 102° to 104° F. It was somewhat reduced by antifebrin from time to time.

Both shoulder joints soon became painful; and a chill occurred on the 13th.

February 24. I saw him in consultation with Dr. Bartleson. The toe was scarcely at all red. It was moderately tender, and a small opening existed at the site of the wound with a very slight discharge.

Manipulation of the toe, however, showed me that the joint was hopelessly diseased; the cartilages were gone; the grating of the bone was very perceptible on the least movement, and the ligaments were entirely destroyed. I immediately amputated the toe at the metacarpo-phalangeal joint. The wound healed kindly within a week without any inflammation. Both shoulders were tender, but not visibly inflamed or swollen. A few days later both knees became tender. The pain in both shoulders and knees yielded to an ointment of equal parts of ichthyol and agnine. His temperature under quinine (twenty grains a day) ranged from 102° to 103° until March 3, when it again rose to 104°, accompanied with much sweating, but no further chills. Antifebrin moderated it, but produced such exhausting sweats that its use was abandoned. He had, also, complained of a moderate pain in the belly, with slight tenderness. He had had no intestinal troubles.

March 5. He was suddenly seized with right hemiplegia; became unconscious early the next day, and died at 8 P.M. on March 6.

Post-mortem examination March 9, 1888, at 3 P.M., sixty-seven hours after death, Drs. William Osler and George Dock assisting. The body was emaciated; *rigor mortis* well marked.

Chest.—There were two drachms of fluid in the pericardium. There was a slight ecchymosis on the left side of the heart anteriorly near the apex; the heart was filled with blood almost entirely fluid; the right side showed endocarditis, with abundant vegetations on the three tri-cuspid segments. Some of the chordæ tendineæ of the anterior flap were destroyed. The ecchymosis corresponded to an infarct in the substance of the wall on the left ventricle. The anterior coronary artery was plugged. No vegetations on the left side. There were infarcts at the roots of both lungs, especially the right.

Abdomen.—There was no general peritonitis, but a circumscribed local peritonitis existed on the anterior wall of the stomach,

[1] Read before the College of Physicians, April 4, 1888.

towards the spleen. There were a few small infarcts on the walls of the small intestines and cæcum.

The spleen was enlarged and soft, with one infarct at the upper end, soft, and of the size of a chestnut, with a congested zone around it; one below, pale, the size of a cherry and rather hard. Below this last, four or five small, pale infarcts. Occupying the entire middle quarter, and extending throughout the entire thickness of the spleen, was a large hemorrhagic infarct, with soft dark contents. The rest of the spleen seemed soft.

Kidneys.—Both kidneys were slightly enlarged; stellate veins prominent. Capsules only moderately adherent. Infarcts in each kidney.

Brain.—Pacchionian bodies were very well marked; no meningitis at the base of the brain. Arachnoid slightly turbid. The left tempero-sphenoidal lobe a little yellowish; the left Sylvian artery had firm clots in all three of the main branches, at the point of division; they were greyish white in color, with dark almost black color in parts; one a little yellow. On cross sections of the brain there was found a large apoplectic softening in the corpus striatum of the left side, destroying the entire caudate nucleus, and the anterior half of the lenticular nucleus, with spots of slight disseminated hemorrhage in the posterior half. The internal capsule was slightly yellow posteriorly, invaded by hemorrhage to some extent anteriorly, but generally quite distinct in color from the hemorrhagic nuclei on each side of it.

Dr. Dock made some cultures from the heart and spleen and found only the streptococcus pyogenes, no staphylococcus. Hence probably the multiple thrombi without the septic metastatic abscesses.

Remarks.—It is rare that from so slight a cause, apparently, such extensive lesions in all parts of the body should follow, and especially that septicæmia should set in so early, and violently. Only twelve hours after the injury was received pain existed in the entire leg, presumably from early invasion by the lymphatics; within thirty-six hours after the injury, the left-shoulder joint was involved, the temperature rose to 104.5°, and was followed speedily by a chill, the involvement of other joints, and, after a comparatively long illness, by death. The infectious endocarditis of the right side was a typical lesion. Associated with this (as has been shown in the history) were infarcts in the brain, heart, lungs, spleen, kidneys and intestines.

This case may teach us two most important lessons: 1. The danger of delay even in slight wounds. Three hours elapsed between the receipt of the injury and any surgical attention, and that of the most superficia character. Within that time doubtless the mischief began. The local trouble, however, was at no time serious in external appearance. When I first examined the foot on the 15th day and found the joint entirely destroyed, with the exception of a small almost uninflamed opening caused by the splinter, and a drop or two of pus, the toe looked perfectly normal. Yet even in so casual and apparently unimportant a wound with so little local trouble the infective process ran an extraordinarily rapid course.

2. It teaches us the absolute importance of careful, thorough and antiseptic surgery. The proper course to pursue would have been to etherize the patient (or cocaine might have been used), and to make a free incision at the site of the wound, so as to be sure that the entire splinter was removed immediately; and, as the wound was so near a superficial joint, to determine the fact whether this joint was involved or not.

Next, and equally important, the wound should have been most carefully disinfected, and an antiseptic dressing applied. Had the patient sought surgical advice at once, and had thorough surgery and careful antisepsis been used, it is probable that he would have recovered without any serious trouble.

That he was personally a blonde, with a suppurative tendency; that his father had suffered for eighteen months with suppuration following an injury near the knee from a tack, and that his sister had suffered for six weeks from a palmar abscess, make it possible that suppuration, and even death, might have occurred in spite of the utmost precaution. But the existence of this tendency, personally, and in the family, would be the very strongest possible reason for *extra* precautions to prevent any septic trouble.

Until surgery becomes an exact science (a comsummation in the far distant future, I fear), we cannot say that a different result would *certainly* have followed had antiseptic methods been used; but we *can* say, that without them he was certainly doomed to trouble, and even, as the result showed, to death; and that with them his chances would at least have been extremely good.

The culture experiments of Dr. Dock were of interest, showing the nature of the infective coccus present.

—The *Lancet*, April 14, 1888, announces the publication of a weekly journal called the *Nursing Record.*

A CASE OF MULTIPLE NEURITIS (SPORADIC BERI-BERI?)

BY G. BETTON MASSEY, M.D.,

PHYSICIAN TO THE NERVOUS DEPARTMENT OF HOWARD HOSPITAL, PHILADELPHIA.

The comparative rarity in this country of typical cases of multiple neuritis, unconnected with diphtheria or with arsenical, saturnine or alcoholic poisoning, and recent changes in the views of the pathological nature of certain palsies and atrophies, renders the details of the following case worthy of special record. That a recovery from the acute attack has prevented our adding the post-mortem appearances to the clinical details, is doubtless largely due to the appropriate treatment of the onset of the disease by the attending physician, Dr. B. C. Snowden, of Olney, who subsequently referred the patient to my care.

By way of preface, it may be added that we were totally unable to assign an adequate cause for the attack of this unique disease, unless, as suspected by Dr. Snowden, the first manifestations were rheumatic, and the attack itself a sequel. There was, however, no rheumatic history whatever preceding the pains of the attack. As to the influence of cold and damp, this could be easily assigned considering the exposure incidental to the patient's occupation as a farmer; but, on the other hand, the first attack was in August, and neither could be traced to any unusual exposure. The question of poisoning from various sources was early canvassed, with negative results.

M. W., a vigorous and robust farmer, aged 30, married, had always been in the best of health until the present attack. His mother died of laryngeal phthisis at 66, his father of paralysis of the stomach at 67, and a brother of phthisis at 26. Three brothers and two sisters are living and healthy, save that one brother is troubled with hay-fever. No other relatives have been the subject of nervous diseases.

In August, 1887, while putting a bridle on a horse, his arms showed sudden weakness, and he experienced pain and soreness in the right biceps. This increased in severity and lasted for several days, and at the same time was accompanied by similar pain and weakness in the left leg and foot. The foot became œdematous, especially over the instep, where it was also red and exquisitely tender. He was confined to the house several days, but the pain and paresis lasted five weeks, leaving the arm and leg atrophied and weakened. From this time until early in January, 1888, he continued to improve in the two weakened members, which felt worse after prolonged exercise and in the morning, and evening, being "eased up" by motion. In December, had an attack of diarrhœa. On January 13, 1888, while in the field, his feet began to pain him, and he noticed weakness in both legs below the knees. He continued to supervise the work for the remainder of the day, although the legs and feet were unusually cold. That night he found he had lost the power of motion in all of the toes. He slept well, and in the morning was assisted to sit up and dress by his wife, but on attempting to stand fell back suddenly on the bed. Being a man of great persistence, he at last succeeded in going down stairs with his wife's assistance, and ate his breakfast at the table. He then attempted to go out alone, managing to get twenty yards from the door when he fell helpless and was carried back to the house. It is thought that at this time he fainted, as he did not recognize Dr. Snowden when the latter reached him, although he recognized a clergyman who called later. He passed a comfortable night with pain in the legs only, and sat up in the morning with help, but the pain in legs and arms became worse and continued most intensely for five days. There was a dropping and tingling sensation with great soreness accompanying the pain in the forearms and legs, and total paralysis of the arms below the elbows and of the legs below the knees. He could flex the arms slightly and move the shoulders and all trunk muscles, but could not feed himself for two weeks. In three weeks he got on his feet with assistance, and attempted to step in seven weeks, but would fall suddenly after a couple of steps had been taken. At no time during the attack was there girdle sensation, disturbance of the bladder or rectum, or pains about the body.

At the end of eight weeks, his condition remaining somewhat stationary, he was placed under my care, being admitted into my private hospital March 8, 1888. His condition on admission was as follows:

Beyond slight emaciation, his general health was good, bladder and urine normal, bowels somewhat constipated (an old habit) and complexion good. Being unable to walk, he was carried into the institution. He could make all movements of the wrists and hands, but they were too weak to handle a knife in cutting up food, or even to press the spring of an electric button. Dynamo-

meter zero for each hand. Movements of elbows also feebler than normal. No movements in toes of either foot, nor in the extensors of the foot; slight movement in the calf muscles. All movements of the knees, hips and trunk normal, except in the gluteal and hamstring muscles, which are feeble; limbs soft, flabby and wasted.

The electric reactions were exceedingly interesting, showing not only the degeneration reaction in the completely and partially paralyzed muscles, but also slight shades present in muscles of the arm that responded normally to the will.

Nerves.—The ulnar and median nerves of both arms and the peroneal and posterior tibial nerves of both legs showed marked De. R., no strength of the Faradic current producing the least response, and the serial and modal changes in the galvanic response being marked.

Muscles.—The intrinsic muscles of the hands and feet showed the most profound change in electrical behavior, no response whatever appearing to Faradic currents, the galvanic response being quantitatively increased and the normal order transposed to An. Cl. C″—Ka. Cl. C′. The minimal anodic closure contraction appeared at 3 ma., the kathodic at 5, with a large active electrode. The modal change was even more profound, the response occurring in a slow, wave-like manner. Similar conditions in lessening degrees were found in all muscles of both arms below the elbows and in the ant. tibial and peroneal groups of muscles of both legs. In the left leg the calf muscles were also unresponsive to the Faradic current, and showed galvanic changes, but in the right calf a slight glimmering response appeared to the Faradic. The hamstring muscles showed partial De. R., although responsive to the will, which was also true of the gluteal muscles. The quadriceps muscles of each thigh responded normally to both currents. Above the elbow, the arm muscles showed slight diminution of the normal Faradic excitability. All other muscles of the body were normal.

Sensation.—There was some hyper-algesia on the anterior surfaces of the leg, and diminished tactile sense on the dorsal surfaces of the feet. The tactile sense was normal in the hands and arms, but the pain sense was slightly diminished on both surfaces of the hands. The patient had not suffered from pains for some time before admission.

Reflexes.—The knee jerk was abolished in both legs, and the cremasteric reflex was absent. The skin reflexes were unaffected.

Nutrition.—The finger-nails and the toenails showed no change in rate of growth. The skin was not glossy as in isolated neuritis, but there was extensive exfoliation of the cuticle on the plantar surface of the feet.

Appropriate doses of strychnia, pyrophosphate of iron and quinia, which he had been taking, were continued, and he was put on labile applications of the galvanic current —20 to 30 ma.—daily, massage, the salt glow and almost absolute rest. At the end of four weeks the following improvements in his condition were noted: Dynamometer, right hand, 10 pounds; left hand, 16 pounds. He was able to walk down stairs with but little assistance. The third and fourth toes of the left foot and the right little toe moved slowly to the will. The Faradic current now produced a faint glimmer in the anterior tibial group of the right leg and in the right hamstring muscles. In the left leg faint contractions to this current appeared in the peroneal, gastrocnemius and hamstring muscles, but none in the anterior tibial. The patient's home affairs demanding his personal attention he was compelled at this point to intermit further treatment and return home, able to attend to his business to a certain extent.

There is no doubt that cases of this sort have been frequently mistaken for anterior polio-myelitis of the adult, the paralysis and electric reactions being in some respects so identical, but the facts that point to a purely peripheral neuritis of the affected nerves in this case are: The escape of the anterior muscles of the thigh which were almost invariably involved in the large number of cases of polio-myelitis that have fallen under my observation, and the fact that *all* the muscles supplied by the sciatic nerves were more or less affected. In polio-myelitis associated muscles supplied by different nerves are similarly affected by disease occurring at the center of the association in the cord (the large ganglion cells of the anterior cornua); in multiple neuritis the muscles supplied by a certain nerve are attacked, and those supplied by the most distal parts of the nerve fare the worst.

Speculation as to the cause of this attack has been so far fruitless, the only reasonable supposition involving a sporadic case of a microbic disease, such as is said to be endemic and at times epidemic in parts of India under the name of beri-beri, and in Japan under the name of kak-ke.

1706 Walnut Street, Philadelphia.

THERAPEUTIC VERSUS MEDICAL DIAGNOSIS.

BY L. HUBER, M. D.,
ROCKY FORD, COLORADO.

The comprehension of the history, cause, and development of symptoms in any particular disease is embraced under the term *medical diagnosis*. In other words, medical diagnosis is simply a cognizance of particular diseases in their entirety. This power is essential to the classification of diseases. It is a kind of synthetic process that the trained mind readily performs. Over and against this, there is another mental process highly useful to the practitioner of medicine. It is *therapeutic diagnosis*—a species of analytic knowledge that comes with experience.

To distinguish these two processes, and accord each its place, I will cite a case. Arther R——, aged 11, was brought to me suffering from attacks of diarrhœa. Practically, this was the only thing of which he complained. In investigating the case I found these conditions: Pain in the lower dorsal region, preceding the diarrhœa; tenderness over a circumscribed area of that part of the spine; when the diarrhœa supervenes, there is entire loss of power to control the evacuations. After these attacks all these symptoms abate for a day or two. From these data I conclude the case is one of circumscribed congestion of a portion of the spinal cord with partial paralysis of the inhibitory functions of the lower bowel. This is not a classifiable disease, but rather a *disease-condition*. My *therapeutic* diagnosis considers it as such. I now look upon the diarrhœa as a symptom with an outlying cause. This is different from considering it a disease, the cause thereof lying in or directly acting upon the intestinal canal or some of its auxilliary emunctories. In applying remedies I regard the therapeutic diagnosis solely. I endeavor to remove the causative spinal lesion. Ergot and belladonna are administered and a direct result is obtained. This confirms the view taken and the correctness of the analysis made. Other remedies had been fairly tried, before this case came into my care, but without any effect, furnishing therein a still further confirmation of the correctness of the therapeutic diagnosis.

Again, among chronic phthisical patients, there are occasionally present attacks of dyspnœa. These may be mild or severe. In those cases in which there is considerable solidification or contraction of lung tissue, with very little softening or breaking down of the same, this mild dyspnœa is attended with an unbearable, irritable heart-action. This latter condition may be interpreted in two ways. First, it may be due to capillary congestion of portions of the lung tissue. The feeling of weight and discomfort over the affected portions of lung would strongly indicate this condition. Moreover, a moderate hemorrhage now and then, when this sensation is experienced, often relieves not only the feeling but also the dyspnœa and the belabored heart-action. On the other hand, the volume of circulation in a consumptive being diminished, the tone of the system lowered, and consequently the accelerative force of the heart weakened, mild congestion passive in character, and dyspnœa naturally follow. Whichever view be adopted, it follows that the medication must be somewhat different. The writer inclines to the first chain of phenomena given. These constitute his *therapeutic diagnosis*. Accordingly he obtains good results from cimicifuga, or ergot, or he combines a few drops of aromatic sulphuric acid with small but frequent doses of digitalis. He aims to remove the congestion of lung tissue, and accomplishing this the dependent symptoms quickly disappear. It is true the remedies employed are not without their regulative effect upon the cardiac apparatus. The case, however, shows the point in question, viz.: the difference between the medical diagnosis, which makes the disease to be phthisis pulmonalis; and the therapeutic diagnosis, which analyzes the present condition of the patient and suggests the proper remedies to improve it.

The two terms are placed at the heading of this article as apparently antagonistic. This is not meant. They are simply conceived to be contrasted. Both medical and therapeutic diagnosis are essential to success in medicine.

The extensive experimental study of physiology at the present time, the development and adoption of the physiological rather than the purely clinical study of therapy, the greater familiarity of the profession with the natural history of many diseases, all combine to simplify therapeutic diagnosis. These facts find an illustration in the symptomatic and antiseptic treatment of certain fevers. Suppose two physicians hold counsel in a case of typhoid fever, in which the temperature has risen above the safety limit. Both agree in the medical diagnosis as to typhoid, but as to therapeutic diagnosis they differ. One proposes for the reduction of temperature quinia in large doses, or veratrum viride, or

the tepid or cold bath. The other looks upon the hyperpyrexia as due to a large amount of septic material being absorbed from the intestinal tract, and proposes the bath for temporary relief, and antiseptic agents, as carbolic or some other acid, or iodine, to destroy the toxic matter.

The field of therapeutics has always afforded many and warm contentions. Were disease conditions better described and remedial agents selected and classified accordingly, by our standard authorities, it is certain that there would be less difference of opinion. Works on practice too often stop with general principles. Medicine having grown up as an empirical science, the principles are inductive. The student in order to comprehend these generalizations must comprehend the body of facts from which they are deduced. Hence the treatment of particular diseases should be written up on the basis of therapeutic diagnosis.

Within recent years great improvement and progress have been made in works on therapeutics, mainly in that individual agents are studied and their physiological effects carefully recorded. Moreover, their therapeutical applications are given rather in reference to disease-conditions than diseases in their entirety. In other words, therapeutic diagnosis is regarded, and remedies described accordingly. That this is a mark of progress few will deny after reading what has been previously said.

DIPHTHERIA.

BY P. J. FARNSWORTH, M.D.,
CLINTON, IOWA.

Very little, if any, advance has been made in the pathology or treatment of diphtheria since Bretonneau investigated it in 1826. Nearly all the modern literature follows him very closely, both in description and treatment. We have changed our form of iron, and perhaps added chlorate of potash, but that was the fashion twenty-five years ago. Besides that, we ring the changes on stimulants and supporting treatment, and assert that it is a local disease with constitutional symptoms, or a constitutional disease with local symptoms.

It appears in widely separated localities, though it seems to have made its home in some of the large cities. The mortality in some epidemics is forty or fifty per cent., then it comes down to four or five, and the practitioners give themselves the credit of curing the disease, and rush into print with their methods: iron, chlorate of potash, alcohol, bichloride, or mild chloride, of mercury, with or without local treatment. It is probable that as many cases would have recovered with some attention to ventilation and lemonade for medicine, as from all the so-called successful treatments.

There are many reasons for supposing that it is at first a local disease, arising from some spore floating in the atmosphere, finding lodgment and an appropriate soil in the throat. It sometimes plants itself on a burned or blistered surface, when there is no disease of the system. When bacteria were discovered as the cause of disease, the bacterium or micrococcus of diphtheria was sought, and found in abundance, on and about the membrane, but contrary to expectation these when transplanted would not produce the disease. The membrane may be transplanted and flourish, but the microbe is an accompaniment rather than cause—something that seems to follow.

The membrane under the microscope appears like a coagulum growing in the substance of the gland, involving the mucus tissue and having beneath a fibrous tissue. If these are not the roots of the membrane they are exhausted or necrotic fibrin. It is thrown off or may be pulled away, and a new membrane forms on the denuded surface. On an abraded surface on the outside of the body the membrane has the same appearance to the naked eye. I have never had an opportunity of examining any with the microscope. Effectually destroying this membrane cures the disease; perhaps if allowed to remain it would produce the same constitutional symptoms that it does in the throat. Some peculiar condition of the surface, either alkaline or acid, or a condition of inflammation, is required for the cultivation of the disease, for many throats and many blisters escape it during an epidemic. A mother in my practice had diphtheria severely; the membrane formed and reformed many times on the tonsils, and then passed down the trachea. It was coughed up in ribbons and then in a cast coming from as low down as the bifurcation of the bronchi. From weakness partly, and from extension of the membrane into the lungs, she died. Three days before death I found her nursing her child. Neither the infant nor another child, nor any member of the family had the disease, and no precautions were taken to prevent it. Yet when a sister came from a country where there was none of of the disease, forty miles away, to assist at the funeral, she took it in a week, having it in a mild form. It was in cold weather, and the

disease spreading from this patient followed one street of the city, until there were a hundred cases, and forty deaths. Some sporadic cases followed the next year, but since then the city has been free from it for ten years. It prevails in many towns of this State, and in some in a virulent form. In some places it has lingered two or three years. It is not a disease of filth or sewage; it goes into the best houses and the healthiest parts of towns. I have made the suggestion that it is a fungus of a higher order. Will some one who has knowledge and opportunity direct his attention to it and endeavor to elucidate some new law that will lead to new treatment?

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, April 5, 1888.

Thomas M. Drysdale, M. D., in the Chair.

Dr. T. M. Drysdale reported a case of

Multilocular Papillomatous Tumor of the Broad Ligament; Operation; Death.

At the request of her physician, Dr. A. G. B. Hinkle, I was sent for Jan. 7, 1888, to see Mrs. M. I. K., a widow, 54 years old. She stated that she was the mother of seven children, and that her labors had invariably been hard and tedious, accompanied with violent abdominal cramps. The menopause occurred when she was 46 years old. She had always been strong, worked hard, lifted heavy weights, and had had no sickness in thirty-five years until last March, when she was seized with intense pain in the abdomen, together with obstinate constipation. She continued to suffer for several weeks, and her physicians had great difficulty in getting the bowels moved. Medicines had so little effect that her life was despaired of, but she was finally relieved by copious purgative injections. Her disease was at first supposed to be owing to sewer-gas poisoning, as her son suffered in a similar manner at the same time, and they were treated accordingly, but finding they did not improve a consulting physician made a more thorough examination, and found well-marked blue lines on their gums. They were then treated for lead colic, and soon recovered. The son had remained well ever since, but she had suffered from colic and constipation, while the abdomen had continued permanently swollen. Her bowels never moved satisfactorily, as only a portion of the contents seemed to come away, leaving the upper part of the intestine full. Last August she first felt a hard tumor low down in the right side. Her abdomen since then had increased rapidly in size, while the rest of the body emaciated. Her appetite had been good, and she had no pains after her meals, but felt too full to eat much. She had constant eructations, but no vomiting. Until recently she had a slight daily movement of the bowels, but for several days past she had had no evacuation. During all this time she had suffered from what she supposed was colic, and, in fact, was never free from pain. Just before I saw her she had taken a dose of castor-oil, and at my visit was in great agony at the distention.

She was thin and anæmic, and her complexion had the cachectic appearance of malignant disease. The centre of her tongue was red and smooth. The abdomen was greatly enlarged, and resonant on percussion everywhere, except below a line half way between the umbilicus and pubis; there it was dull, and fluctuation could be detected. In the right iliac region I found a hard nodulated tumor which appeared to be moderately movable, but so rigid was the abdominal wall that it was difficult to determine this with certainty. The bladder was prolapsed and projected between the thighs, but the uterus remained within the shortened vagina, and was held up apparently by being fixed to the tumor. The uterine sound entered two inches, and passed to the right. As well as could be made out, the uterus and tumor were closely adherent. Rectal examination revealed a firm, immovable tumor occupying the upper part of the pelvis. The examination, although made with the utmost gentleness, caused great pain. As frequency of micturition was a prominent symptom, Dr. Hinkle had more than once examined specimens of her urine, but, finding nothing abnormal, concluded that the irritation was owing to the prolapse of the bladder. As usual before an operation, I also examined two specimens of the urine, and found it free from albumin and sugar, with a sp. gr. of 1020. She assured me that she passed the usual quantity.

The oil operated and gave her relief for twenty-four hours, but after this she grew rapidly worse, the symptoms of obstruction of the bowels increased, and by January 17, just ten days from my first visit, I was again sent for, and found that she had been in such continual agony that she had concluded

to submit to an operation. The abdomen was extremely hard, and in place of being tympanitic, was everywhere dull on percussion and fluctuation was general, showing that a rapid effusion of fluid had occurred.

In the presence of Drs. Hinkle, James F. Wilson, I. Howard Beck and G. B. McCracken, and assisted by my son, I operated January 22, 1888. The incision was followed by the escape of about a gallon of ascitic fluid. The peritoneum was slightly inflamed, and in some parts thickened. The growth proved to be a multilocular papillomatous tumor of the broad ligament. It filled the lower part of the abdomen on the right side, and occupied the upper portion of the pelvis. Its color was not the opaque white of an ovarian cyst, but resembled in this respect the intestines. The main cyst extended upwards as high as the border of the lower ribs. To this the omentum and a loop of intestine were firmly adherent. These adhesions were detached and the cyst drawn forward. As this was being done it burst and discharged a large quantity of red serous fluid; for, as usual, the cyst walls were very thin and easily ruptured. Two other large cysts below this were tapped, which greatly reduced the size of the tumor, but a mass of others remained, filling the upper part of the pelvis, to which they were firmly adherent. This was the portion which, by pressing on the bowel as it passed the pelvic brim, obstructed it. Here it was difficult to separate the tumor from the surrounding structures without injury to them, for it was adherent to the bladder, bowel and everything it touched. After freeing it from all its other attachments without doing mischief, save to some vessels on the floor of the pelvis, which bled profusely, I found it was firmly bound to the uterus, which it dragged down and held close to the anterior wall of the pelvis, deep down on the right side, by an exceedingly short, firm and vascular attachment or pedicle, which I ligated with great difficulty, owing to its depth in the parts. The tumor with its capsule was then removed. This revealed a set of bleeding vessels below the pedicle, which were secured after considerable trouble. Before closing the wound the abdomen was thoroughly cleansed by irrigating it with warm water which had previously been boiled. The operation was tedious, lasting over an hour, and through it all the pulse was well maintained, but it was followed by a profound shock, shown in the pale face and thready, almost imperceptible pulse. As soon as she became conscious she complained of intense pain in the back. Under the use of stimulants and the external application of heat she reacted in about an hour.

At 5 P. M., four hours after the operation, the nurse applied the catheter and removed an ounce and a half of urine. At 8 P. M. Dr. Hinkle and I visited her and used the catheter, but the bladder was empty. Her pulse was 112, temperature $100\frac{1}{5}°$, which was the highest it reached. She complained of feeling sore all over. To relieve the suppression of urine, we ordered a mustard plaster, made with warm water, to be applied over the kidneys, and prescribed a tablespoonful of the following mixture, well diluted with water, to be taken every four hours:

℞ Potassii ascetatis.....ʒss
Spiritus ætheris nitrosi.....fʒss
Aquæ destillatæ.....fʒiiiss

10.30 P.M., she vomited for the first time. 12.15 A.M., after an ounce of urine was drawn, she became restless and complained of severe pains in the abdomen, which continued until Dr. Hinkle was sent for at 2.15 A.M. He found her with a pulse of 94, and a temperature of 100°, and gave her a hypodermic injection of one-sixth of a grain of morphia. After this she slept until 5.30 A.M., when the nurse drew her urine and obtained ʒss.

Monday, 10.45 A.M., pulse 118, temperature 98°. Since 7.30 A.M. had been in pain and had vomited several times. The catheter had just been used and about a teaspoonful of urine drawn. The abdomen was tympanitic, but not tender on pressure. The rectal tube was used which permitted a large quantity of flatus to escape. After this the diuretic was used by injection and retained. We directed one drachm of Rochelle salt to be given every two hours and, a hot vapor bath. 2 P.M., pulse 130, temperature 97°. Had vomited everything. A quarter of a grain of calomel and a tablespoonful of very hot milk were then given every hour. This quieted her stomach. At 4.50 P.M., one ounce and a half of urine was drawn. She continued drowsy but did not sleep. 9.30 P.M., one drachm of urine was removed.

Tuesday, 10.30 A.M., pulse 130, temperature 96°. Skin cool and pale. The catheter had been used at 2 P.M. and at 9 A.M., and each time about a teaspoonful of urine was obtained. The stomach continued quiet, until 9 A.M., then she vomited occasionally. Stimulants were used by the rectum, but she continued to sink and died at 6 P.M.

The autopsy was made the next evening by Dr. McCracken, who kindly furnished me

with the following notes of it: "The wound in the abdominal wall was firmly united throughout the whole extent. A moderate amount of peritonitis existed, confined principally to the lower part of the anterior abdominal wall and the lower coils of intestines, which were covered with a thin layer of pus. This was the portion of the peritoneum which was found inflamed when the abdomen was opened at the operation. The pedicle and surrounding parts from which the tumor was detached were in excellent condition. The right kidney was sought for but could only be detected after a prolonged search, when it was found to have been converted into a large, elongated cyst, only a small portion of the upper part of the organ remaining unchanged. It resembled a distended bowel so closely that it was difficult to distinguish it from the surrounding intestines. The left kidney was enlarged and intensely congested. When the adherent capsule was removed, the surface of the gland presented the rough granular appearance of inflammation. There were a number of small cysts in the cortical substance."

This case presents several features of interest, one of which was the steady decline in temperature from 100⅕° on Sunday to 96° on Tuesday morning. But I have brought it before you mainly for the purpose of showing how we may be deceived in regard to the condition of the kidneys, even when all signs of disease are absent in the secretions. This patient's life was dependent upon the active exercise of one organ, which itself was diseased and struggling under the load thrown upon it as the only eliminator of its kind in the body. It naturally followed then, that when the toxic effect of the ether was added to its burden, it yielded and the patient died.

Dr. Parish spoke of the toxic effect of ether on diseased kidneys and wished to know whether Dr. Drysdale had been able to determine the renal condition in this case. He had some years ago had a case of Porro-Meuller operation in which there was parenchymatous renal disease, and in which death resulted from acute suppression of urine. It was a serious question as to what anæsthetic we should use under similar circumstances. The tumor presented by Dr. Drysdale was peculiar for a cyst of the broad ligament, on account of the large amount of solid matter connected with it.

Dr. J. Price said there was but one authority who made any mention of the condition of the temperature under ether. Some years ago Dr. Burk had taken the temperature of a large number of patients under the anæsthetic, and found that there was invariably a depression of from one to two degrees, due to cessation of combustion. The symptoms of obstruction of the bowels as presented by Dr. Drysdale's case were very characteristic. He had lately been dealing with some very trying cases of this kind, and pain was always present and very severe; in several cases shock and collapse had been marked symptoms of the obstruction.

Dr. Drysdale did not think that the decline in temperature was due to the anæsthetic, but believed it depended upon the uræmia, as he had repeatedly noted a similar depression in advanced stages of Bright's disease. The urine had been examined several times and nothing found to indicate disease of the kidneys; in fact, there was not a single symptom present to excite suspicion of trouble in these organs, except the constant inclination to micturate, for which the prolapsed bladder was sufficient to account.

Dr. Parish presented the

Specimen of a Strangulated Ovarian Cyst,

and said: The patient was not aware that anything ailed her until one night she was seized with intense abdominal pain, and, jumping out of bed, rushed about the house screaming with her suffering. Dr. J. H. Musser was sent for and gave her a hypodermic injection of morphia. The dose had to be repeated frequently, and in two days the pain began to subside, it being altogether gone in five days. The temperature remained nearly normal until the fourth day, when it was found to be 103°, and was the same on the next day, the day of operation. A notable fact is that the temperature and pulse both rose steadily while the pain as steadily decreased after the third day. I saw her on the fourth day and agreed with Dr. Musser that we had an ovarian tumor with a twisted pedicle to deal with. Because of the absence of the husband, the operation was not performed until the next day, Jan. 17, 1888. The tumor was found to spring from the left ovary, and was very black, in this respect differing entirely from an ordinary ovarian cyst. The contents were those of an ordinary cyst with coagulated blood in addition. The pedicle was twisted three times and was quite soft and black. After emptying the tumor he untwisted the pedicle and transfixed it below the point of twist, and the tumor was removed. The recovery was very rapid, the temperature, going down steadily. The drainage-tube was removed on the second day. The patient is now entirely well.

Twisting of the pedicle is a well recognized accident to ovarian tumors, but the cases do not all present such marked changes as this case did. The specimen as it lay on the plate presented a very marked contrast to the cyst lying beside it, and which had been removed a few days before from the broad ligament.

In connection with this case he would report one operated on three months ago. The woman had complained of sudden intense pain in the pelvis, and was confined to her bed from that moment. She had remained in bed for over two months with general peritonitis. A number of physicians had attended her, and one of them had introduced an exploring needle into the abdomen. She was extremely exhausted, and had a constant temperature of 103° or higher. An incision was made above Poupart's ligament and opened into a tumor. It was found to contain pus and coagulated blood. Its cavity was cleansed out and the incision closed around a drainage-tube. The cyst walls were very thick. It was a blood cyst; but it could not be determined at the time with certainty whether it was intra- or extra-peritoneal, but it was believed to be intra-peritoneal. In three days strangulation of the bowels developed with fæcal vomiting. The bowels could not be gotten open and a second operation was proposed on the next day, but was refused by the friends. On the day after, however, a second incision was made from a point under the spleen towards the old incision above Poupart's ligament. There was a distension of the abdominal walls in the right lumbar and hypochondriac regions. Great pain under the spleen had developed. The intestines were found adherent in a mass, and three large bands were found to extend from the region of the spleen to the right inguinal region. The adhesions were broken up, and these bands were ligated and cut off. No irrigation was used. The whole wound was closed and a large piece of adhesive plaster was placed over it to protect it from the discharges from the lower and first incision. Convalescence was a slow one, but had finally terminated satisfactorily.

—The *Medical Record*, April 21, states that the Essex County Medical Society has begun a war upon the physicians practising in Newark, N. J., who have not proper diplomas to practice, and the Committee on Illicit Practice has been directed to secure the indictment by the Grand Jury of three persons who have, it is alleged, no legal status as physicians.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, April 5, 1888.

The President, A. Jacobi, M.D., in the Chair.

A Contribution to the Diagnosis and Surgery of Cerebral Tumor.

Dr. E. C. Seguin and R. F. Weir made the contribution.

The first part was devoted to the description of a case. The patient was a resident of Bridgeport, thirty-nine years old, who in 1882, when he had malarial fever, with a good deal of pain in his head. His wife one day noticed spasm of the right cheek and neck. This was the "signal symptom." Consciousness was not lost. He had one or two similar attacks up to 1885, but the man's wife felt sure that there had been no spasm extending down to the right arm or hand until that year. In 1885 the symptoms of cerebral disease became more marked. One day that year he fell, became unconscious, bit his tongue, and probably had a general convulsion. He had had similar attacks at long intervals since. These epileptic attacks were preceded by an aura. There was no history of epilepsy earlier in life, nor of syphilis. The epileptic attacks were always preceded by twitching and jerking in the right face, arm and hand. The patient was brought to Dr. Seguin in August, 1887. Memory was not as good as formerly; speech had become thick; the general health was good. After this date the symptoms grew rapidly worse until the operation, November 17, 1887. He felt a numb and heavy sensation in the right upper extremity. The tongue was tremulous, and projected a trifle to the right. Paresis in the right arm and hand grew more pronounced, until the strength was about two-thirds that of the left. After the patient was first seen by Dr. Seguin, a local pain developed over the motor zone on the left side. The symptoms did not extend downward, nor to the left side. Two days before the operation the temperature over the scalp was carefully tested, but the result of the examination was considered negative. The diagnosis of a tumor in the motor zone on the left side was made. They were uncertain whether it was cortical or subcortical. The saliva escaped from the right buccal angle. There was some loss of muscular sense in the right hand. The eyes were normal.

Dr. Weir performed the operation November 17, making the center of the opening the

auriculo-bregmatic line and the middle of the motor zone on the left side. The trephine was used at two places, and the opening being joined, the dura mater was exposed a distance of two by three inches. At first no abnormal condition could be discovered; but afterwards, when deep pressure was made, a resisting body was felt, which proved to be an infiltrating sarcoma of the size of an almond. Brain substance of the size of a pea was all that was lost. The patient left the hospital for home one month after the operation. His symptoms since then have varied, being worse when he was suffering from malarial or intermittent fever. There was almost complete right-sided hemiplegia and aphasia just after the operation; it was nearly a month before he had another convulsion. The patient's condition differed little at present from what it had been before the operation, but Dr. Seguin felt convinced that there had been improvement in sensibility, both of the face and hands, while the wife said the twitching in the muscles of the face had ceased. The aphasia was about as it was before the operation. The mental symptoms did not show any increased intracranial pressure or relapse of the sarcomatous growth. Dr. Seguin thought the tumor, although situated about an inch below the surface of the brain, might have involved to some extent the cortical substance of a deep convolution in that neighborhood. He thought the operation had prolonged the patient's life.

The remaining part of Dr. Seguin's contribution was an application of present knowledge to the diagnosis of cerebral tumors, especially of cases suitable for surgical interference, while Dr. Weir reviewed cases operated upon. Dr. Keen, of Philadelphia, then gave a part of the history of a case of large cerebral tumor removed by him last fall. The patient still survived.

—The *Phar. Record*, April 1, 1888, states that soapstone incorporated with oil, after the manner of a paint, is said to be superior to any kind of paint as a preservative. Soapstone is to be had in an exceedingly fine powder, mixes readily with prepared oils for paint use, covers well surfaces of iron, steel or stone, and is an effectual remedy against rust. It has been known to protect some stone work, such as obelisks, in China for ages past. The writer who calls attention to this is a scientific expert of London, who has noticed the use of this Chinese soapstone in China, and has been experimenting with it since his return to England.

Foreign Correspondence.

NEWS FROM PARIS.

Recurrence of Cancer.

At the meeting of the French Congress of Surgeons, M. Cazin showed the result of his practice from 1862 to 1886, in reference to the recurrence after operation of cancers of the breast. He attributes the comparatively considerable proportion of his successes to the course of treatment he has always followed, namely, very thorough removal, even when the glands are quite healthy. M. Verneuil said, "Besides the operative precautions so well described by M. Cazin, the means to be employed to prevent the recurrence of cancer are still the subject of study. What have we as a preventive against these complaints? As a rule, a six months' treatment after the operation is the only thing recommended. Nevertheless, I think that these germs, in the embryonal state, may be destroyed or attenuated by medication, which is inapplicable in cases of declared cancer. I recommend, after the operation, a permanent arsenical and alkaline treatment, say $\frac{1}{20}$ grain of arsenic per diem and a teaspoonful of magnesia in a glass of cold water every night, in connection with an entirely vegetable diet. I am aware that M. Reclus is on the point of publishing some important papers on this question; and must admit that cancerous affections are greatly on the increase. It is well known, that since the rural population have taken to eating meat more generally, tuberculosis and arthrites, which foster cancerous growths, have been on the increase." M. Poncet said: "Looking to the whole of the facts brought under observation, he concluded that: 1. Relapse is nearly always fatal in subjects presenting a direct cancerous heredity; 2. When the glands are attacked, the tendency to relapse increases; 3. The best hope of a cure lies in a rapid and thorough ablation. In certain regions no hesitation should be felt in carrying out the preliminary operations, although these might seem out of proportion to the size of the tumor to be removed. 4. It is, however, desirable to abstain from attempting any radical operation under too unfavorable circumstances; numerous cases justify only palliative action." M. Labbé, of Paris, said it was difficult to give an opinion on the question based upon authentic figures, but the opinion of an experienced surgeon might be of some weight. The necessity of com-

plete local and glandular ablations was generally admitted in surgery; yet patients, as a rule, do not readily consent to the removal of a limb to all appearance but little diseased. "A dermoid tumor of the breast, the recurrent tendency of which I pointed out to M. Coyne, is an interesting study. In this, a bare enucleation is notoriously insufficient; it is necessary to go far beyond the enveloping capsule. Furthermore, when such tumors have taken considerable extension, the entire breast has to be removed; and then the remainder of the gland, which is pressed back eccentrically and flattened, has to be sought for; and it is hard to find, as I recently demonstrated to some young surgeons at the hospital. By taking this precaution, the six or seven successive regrowths, in this rather mild form of tumor of the breast, are prevented. I will say a word on immediate auto-plastic surgery, of which I am a warm partisan, especially where the face is concerned, as there ablations, as extensive as required, may be effected. A case I have had under treatment for the past six years, that of a man, from whose face I removed the entire cheek on one side, together with the submaxillary glands, has been attended with perfect success. In partial epithelioma of the face, the application of Côme Bros. *caustic balm* is to be preferred to the bistoury. Finally, I entirely concur with M. Verneuil as to the indefinite treatment to be followed after the operation; and I furthermore recommend the application of Nussbaum's tincture of condurango."

M. G. Richelot stated that, according to statistics, vaginal hysterectomy was followed by more relapses than even epi-vaginal amputation of the neck. This was to be explained by the fact that many surgeons of the present day had advocated partial operation in limited uterine cancer, and only proceeded to hysterectomy in such cases as were not to be operated on without it. He suggested, as a means of diminishing the chances of a relapse, the resection of a strip of the vagina, useful more especially in epithelioma of *cauliflower* or tench-head growth, which has more tendency to propagate on the side of the vagina than on that of the uterus. Respecting incomplete operations upon the uterus, he added that these should only be attempted as a last resort, where the diagnosis was incomplete, and that they should not be performed where it was found that the broad ligaments were attacked. M. Castex, of Paris, recalled a case, followed by post-mortem examination, in which propagation of sarcoma through the blood-vessels was traceable in the cartilage of the knee. A sarcomatous colony, connected with the degenerated synovial membrane by vessels of fresh growth, existed in the middle of the cartilage, which was otherwise healthy. M. Sabatier, of Lyons, believed that, to avoid local recurrences, it was necessary to remove the malignant tumors intact, as true cancerous grafts easily formed on a fresh wound. The danger was all the greater in a primary reunion, which favored the development of these germs; these, on the contrary, were eliminated with the discharges of suppuration in cases of secondary reunion.

M. Mollière, of Lyons, said that in cases of recurrent cancer, the age of the patient had to be taken into account. In children, recurrence was so rapid that serious operations could not be justified. In a woman of 30, a recurrent cancer in the breast was exceedingly dangerous; chances of survival were greatest at 50; and after 70 it might be said that cancer caused no headway.

Speaking of

Ocular Epithelioma and Melanosarcoma and their Recurrence.

Dr. Galezowski, of Paris, said: Malignant tumors of the ocular globe develop more especially in the anterior segment of the eye, a fact explained by the greater nutritive activity existing on the level of the sclero-corneal border. In these tumors the epitheliomata do not appear to be reproduced through the channel of the blood and lymphatic vessels, as they would then be confined to the affected spot from the very first. Like M. Verneuil, I have observed that in the eye, as in many other parts, neoplasms of a malignant type are of far greater frequency than they were twenty-five or thirty years ago. It is, however, easier nowadays to remove such tumors; but it is often difficult to discover the precise spot at which the evil has taken root. In any case, melanotic epithelioma invariably becomes implanted on the edge of the cornea.

Abdominal and Vaginal Hysterectomy for Cancer.

M. Demons, of Bordeaux, stated as his opinion that hysterectomy for cancer is only called for in cases of defined cancer of the uterine body. The lowering of the neck of the uterus is sometimes very difficult when the neck is friable; but newly-invented instruments may now be used in taking a firm fulcrum on the body, as the Museux forceps are inadequate for this. As to the checking

of hemorrhage, a most important question, he did not hold with M. Richelot, who, at the last Congress recommended systematic application on the broad ligaments of the forceps invented by Dr. Péan. It is most difficult to fix the forceps when the uterus cannot be brought down sufficiently. Besides, the forceps do not always prevent the first hemorrhage; and, finally, they have the disadvantage of causing the broad ligaments to slough, retarding the healing process, and determining the elimination of dead tissue, attended with a certain rise in temperature. It has also happened that the ureter and wall of the rectum have been seized by the forceps. The use of forceps may, however, be recommended in special cases.

Dr. Péan informed the Congress that his operations of total vaginal hysterectomy were prior to those of Dr. Demons. Dr. Péan proceeded to say: "Those of my colleagues who contented themselves with following my example in buying ready-made instruments of the maker, should also have attended to the temporary nipping and not exclusively to the definitive action, as the former alone enabled the uterus to be quickly removed without loss of blood. It also enabled the operator, after the ablation of the organ, to draw and bring down the broad ligaments, and if necessary, to take them up in two halves; and this without difficulty or fear of hemorrhage. Furthermore, by its use, ligatures may be dispensed with entirely, if it is sought to make the operation a final one, by leaving the forceps fixed at the spot. Experience has taught me that the reverse of what M. Demons recommends must be done, and that it is when the uterus is small, loosened and easy of removal that ligature should be had recourse to."

M. Terrier found vaginal hysterectomy a difficult operation when he had recourse to ligatures; and, on the contrary, very easy by the fixed forceps method. It was a serious operation, inasmuch as it gave a death-rate of twenty-two per cent. of the cases operated on; it appeared, however, more rational than partial amputation, although this was easier and not originally so dangerous. "I have had seventy per cent. of these cases of relapse under my observation," M. Terrier said, "and effected a cure in thirty per cent. of the cases. To establish the superiority of partial ablation over hysterectomy, statistics relative to the former, drawn up under the same conditions as our own, should be forthcoming; but whatever may be said, such data do not exist."

M. Richelot upheld the fixed forceps method. True, it was difficult of application when the uterus did not descend properly; yet it was in such cases that it was most useful, as ligature under the circumstances was impossible. "I do not believe it retards cure," said M. Richelot; "the only dangerous period is the two days during which the forceps are allowed to remain fixed to the spot; on the third, the peritoneum is closed, as I have ascertained in two *post-mortem* examinations. The patients entirely recover within a week, and may get up in three weeks. I believe that the operation has become so common in France for the past two years owing to the systematic use of the fixed forceps; and the large number of instruments sold by the makers is an evidence of the fact. Abroad even, the forceps are used by Müller, and Landau advocated them at the Congress of German Surgeons."

M. Pozzi maintained that hysterectomy had became an operation sufficiently harmless to be legitimately carried out in all cases previously reserved for vaginal amputations of the neck.

Orthopædic Apparatus.

M. Redard, of Paris, referring to the constructions of orthopædic stays, stated that the best, after all, were those of simple form made by the surgeon. In plastered corsets suspension should be gradual and slow; the patient should be prepared for it several days in advance, and it should never be complete as the the tips of the toes should not leave the ground. If the collar is exactly fitted to the neck and chin, no accidents need be feared. The trunk should be covered with a thin undershirt of elastic material, provided with removable braces, and twice the length of the corset, the lower half of which it should overlap. Salient parts should be covered with strips of white felt. The corset should be made removable in all cases of scoliosis. This apparatus is very light, elastic and durable. For silicated corsets a soft metallic cloth is used with meshes (.156 inch) to be covered by silicated bandages.

The Fourth Congress of French Surgeons will open in Paris on the first Monday in October, 1889, under the Presidency of Baron Larrey, Prof. F. Guyon being Vice-President.

—The new Iowa liquor law requires pharmacists to have a permit authorizing them to administer oaths, and each purchaser must swear that he wants the liquor for lawful use.

Periscope.

Treatment of Colds and Bronchitis.

In the *Therapeutic Gazette*, April 16, 1888, Dr. H. C. Wood discusses in a leading article the treatment of colds and bronchitis. When the cold is a widespread general one, involving the whole body in a condition which he regards as a form of subacute rheumatism, with aching pains and general wretchedness, he advises a free jaborandi sweat, followed by a few full doses of quinine. This, he says, will often liberate the sufferer at once, especially if the sweats are aided by mercurial or other purgation. For coryza, he says bismuth and cocaine injections into the nose almost invariably bring relief, though a vigorous dry shampoo may effect the same result.

In bronchitis, he says, the so-called expectorant remedies are of course indicated. These he divides into three groups: First, the narcotic expectorants, which are to be employed to allay excessive cough and quiet nervous irritability; second, the sedative expectorants, to be used in the first stages of a bronchitis, to facilitate secretion and expectoration; third, the stimulating expectorants, useful in the advanced stages of a bronchitis when expectoration has already become free.

The ordinary narcotics, such as morphine and hyoscyamus, and the advantages and difficulties attending their use, he thinks are well known. Chloroform, however, he regards as one of the most valuable remedies that we have for quieting cough. In nervous or hysterical men or women, often the best expectorant mixture is one composed of pure narcotics. A very good home-made mixture for this purpose is one containing:

Whiskey,
Paregoric,
Glycerine, of each.....f℥ij
Chloroform.....♏ xxx
M. Shake well before using, and take in teaspoonful doses *pro re nata*.

This mixture has, he says, enabled patients to secure many a night's rest, by keeping a little bottle of it, tightly corked, at the bedside, and sipping it when necessary.

With regard to the use of hydrocyanic acid as a sedative, he seems to think that its action is so fugacious as to be untrustworthy in ordinary safe doses; while wild-cherry bark preparations he rejects as certainly useless.

The older depressing expectorants he thinks have little power, unless given in nauseating doses, and in their stead he has come to use very largely the citrate of potassium. Of the following prescription, he says that he thinks any one who will use it will never give it up, unless some new remedy of greater power be discovered:

℞ Potass. citrat.....ʒj
Succi limonis.....f℥iss
Syr. ipecac .....f℥ss
Tr. opii camph .....f℥iij
Syrupi q. s., ad.....f℥iij
M. Sig.—Dessertspoonful every two hours.

This dose is for a robust man, and must be varied according to the strength and peculiarities of the individual patient.

Of the older stimulating expectorants the only ones in which he still places confidence are the muriate of ammonium and the syrup of garlic. When the citrate of potassium mixture fails, he habitually resorts to the muriate of ammonium, and has often seen very good results from its use. It may be given in capsules if the stomach is very sensitive, each capsule to be followed by a drink of water. The following furnishes the best disguise for the taste of the drug that he has been able to concoct:

℞ Ammonii chloridi,
Ext. glycyrrhizæ..... .....āā. ℥iss
Glycerini.....f℥ss
Mucil. acaciæ.....f℥ij
Syrupi,
Aquæ, q. s. ad.....f℥iij
M. Sig.—Dessertspoonful every two hours.

Syrup of garlic is so disagreeable to most patients that it is very rarely used. In his own practice, in ordinary cases, the only stimulant expectorants used besides the muriate of ammonium, are oil of eucalyptus, terebene, and oil of sandalwood, and occasionally oil of cubebs or copaiba. The doses of these remedies are so small, he says, and the taste of most of them so disagreeable, that they should always be administered in capsules. The oil of eucalyptus he is inclined to regard as the most efficient. It may be administered in an ordinary cold or a bronchitis so soon as free secretion has been obtained. Terebene is a little more stimulating than the oil of eucalyptus, and to be employed somewhat later in the disorder (dose five minims). The oil of sandalwood is about equivalent to terebene, while the oil of cubebs is employed still later in the disorder.

Indications and Contraindications of Antipyrin.

At the meeting of the Therapeutic Society of Paris, February 22, 1888, M. Huchard referred to the investigations of Robin and

Casimir, which indicate that antipyrin diminishes the quantity of urine, and expressed the opinion that on this account the drug was contraindicated in certain affections of the kidneys. If it is of use in pure nervous angina pectoris, it is inactive in true angina with stenosis of the coronary arteries. If the heart's action is intermittent, its use may result in weakness of the heart and collapse. In two cases of broncho-pneumonia, Huchard observed grave collapse following moderate doses of antipyrin.

On the other hand, he recommends it in polyuria, on account of its capacity to diminish the quantity of urine. He had under his care a woman thirty-eight years old, who had suffered since her eighteenth year with a meningo-myelitis which followed typhus fever. For several months she drank a great deal and passed as much as 48–56 pints (24–28 litres), of urine a day. The reflexes were heightened, there were violent pains in the limbs and along the spinal column. In order to act upon the nervous system and upon the polyuria, Huchard gave two drachms of antipyrin daily. The quantity of urine diminished in ten days to 10 pints (5 litres) in twenty-four hours. The antipyrin was then stopped, and at once the quantity of urine increased, although not to the same height as before. Up to the present time Huchard has treated only one case of polyuria in this way, but he refers to the fact that Dr. Göllner had obtained improvement in a few days in a diabetic patient through the use of large doses of antipyrin. Huchard holds that antipyrin is proper only in nervous polyuria, while in the polyuria accompanying nephritis, he obtained no result. — *Deutsche Medizinal-Zeitung*, March 26, 1888.

Massage in Alcoholic Asthenia.

Dr. James Barr, physician to the Northern Hospital, Liverpool, in the course of his lectures upon alcoholic asthenia (*Lancet*, January 14 and 21, 1888), remarks upon the efficacy of massage in the treatment of this condition. The muscles, he says, are the great furnaces of the body; in them oxygenation largely takes place, and the effete materials are burned off. It has been truly said that a man digests with his muscles as well as with his stomach; so when we have active muscular exercise the appetite is improved, a greater amount of nutriment is taken in, and tissue change goes on more rapidly. Life implies change; without tissue metamorphosis there could be no life. Some people manage to exist with a small income and equally small expenditure; but their life is that of a sloth; it is mere existence, a sufficient amount of energy to hold the molecules of their composition together, without anything worthy of the name of life. When one wants to restore lost energy he must increase the force, but in order to do so there is no use in supplying the fuel without the fire to light it. There is no use in putting nutrients in the patient's stomach unless he is able to assimilate them. If the muscles are run down and there is no spare nerve energy to make them work, then the places of the nerve current must be supplied by massage and electricity. Massage is a most powerful agent for effecting nutritional changes, and with the increased combustion and greater supply of food, not merely the muscles but also the heart and every organ of the body is nourished, and nerve energy is stored up for future use. He says he has seen a pulse which would not even move the weight of the lever of the sphygmograph, give an excellent tracing with a pressure of five ounces after eight weeks' massage.

What Constitutes a Stone in the Bladder?

In the *British Medical Journal*, Feb. 18, 1888, Sir Henry Thompson takes occasion to state his opinions as to what weight of concretion in the bladder merits the name "stone." The occasion of his communication on this subject is the recent publication of "A Hundred Cases of Stone in the Bladder," by Surgeon-Major O. J. Freyer. With reference to this paper, Sir Henry says: "Among the hundred cases of stone thus reported, I observe no fewer than a dozen cases, the largest of which does not exceed twelve grains, and this not merely in children, for ten of them are adults. But what is more remarkable still, is that a tiny concretion weighing only two grains is twice reported as 'a stone' in the adult bladder, as are also two of three grains each, besides others of four and five grains respectively. Indeed, the total weight of the 'stones in the bladder' for which in eight adult cases 'the operation of lithotrity' has been performed amounts to no more than thirty-seven grains, an average of about four grains each, the total weight of the eight being only that of quite a small stone." Such tiny products, he says, are easily removed for the most part by washing out the bladder, from which, indeed, they usually escape spontaneously. Personally, he never reports a case as one of stone in which the weight of the concretion is less than twenty grains.

Rare Anomaly of the Hymen.

In the *Archiv für pathol. Anat.*, Bd. cxi, Heft 2, p. 386, Feb. 1888, Dr. S. Krysinski, of Dorpat, states that on examining a girl who was suffering from leucorrhœa and some disturbance of the menstrual function, he found an anomaly of the hymen which, as far as he knows, has been hitherto undescribed. It appears that the hymen was pretty thick and round, and that in its left inferior portion there was an opening with an irregular border, which scarcely permitted the passage of a sound 5 mm. (.195 inch) in diameter. In the median line and above this opening there was a projection about twice the size of the latter, which at first glance was taken for the orifice of the urethra. A more accurate examination, however, disclosed the fact that this projection was formed by a duplicature of the mucous membrane of the hymen; in appearance it was not unlike the semilunar valve of the aorta. But from the middle of the free border of the valve anteriorly, it was nearly slit in half. Neither in the inferior nor lateral borders, nor in the posterior surface of the little pocket formed by it, was there an opening present; so that the pocket formed a blind sack, completely shut off, and diminishing in size toward the bottom. The urethra, so far as an examination by means of the sound could determine, opened about one or one and a quarter inches behind the hymen, into the vagina. The urine was passed through the opening in the hymen; but how much this circumstance may contribute toward the development and obstinate persistence of the leucorrhœa, the author says he must leave undecided.

United Fracture of Tooth-Fangs.

Dr. Williamson exhibited recently to the Odonto-Chirurgical Society of Scotland, an interesting case of fracture of the root of a central incisor, which bore evidence of having been united. There was a history of a blow in childhood, from which the right incisor received so much injury that its pulp died, as was shown by its discolored appearance. But both teeth had done good service until the patient reached the age of 45, when the left central became so loose that it was removed with the fingers. A part of the fang, however, was left behind; but, being loose, was easily extracted. On examination, it was found that the two fragments fitted accurately when placed in opposition, except where there was a little chipping at one edge. The fracture of the dentine was at a higher level than that of the cementum, so that the latter formed a sort of collar for the lower fragment. There was some thickening in parts of the cementum, and the whole of the pulp in the coronal fragment was calcified and also the part close to the line of fracture in the other piece.—*Lancet*, Feb. 25, 1888.

Climate and Distribution of Cancer.

In concluding a series of papers on the geographical distribution of cancerous diseases in the British Isles, A. H. Haviland says (*Lancet*, March 10, 1888): "I maintain that those who would give themselves the best chance of avoiding those local conditions which are coincident with a high death-rate from cancer should study well the distribution of this disease in England. There is abundant evidence there to show that cancer does not thrive in high, dry localities, where the soil is kept sweet by the absence of floods, and the nature of the rocks which either underlie it or form its principal constituents; and that it does thrive and become very fatal where floods prevail, where their emanations are sheltered and intensified, where vegetation is killed and decomposed, and where, after the floods have passed away, a rank herbage springs up, composed of sour grass and bitter plants, which scour and otherwise disease the horses, cattle and sheep that feed upon them. Much has to be done, much has been pointed out, and if the twenty-two high mortality and the sixteen low mortality districts were well studied in connection with the various factors which we have seen to be coincident with high or low death-rates, I believe that much would be added, much would be corrected, and much revealed that we little think of now."

The Catgut Suture.

M. Monod, at a meeting of the Société de Chirurgie, spoke on the accidents attending the use of certain kinds of catgut, and cited the case of a Swiss surgeon who had a regular series of accidents—phlegmons, erysipelas, gangrene. He substituted for the catgut carbolized silk, and ever afterwards had union by first intention even in major operations. M. Lucas said that the catgut of commerce should be abolished completely from the treatment of wounds. The carbolized silk was much superior, especially in the ligature of the pedicle of an ovarian cyst. The ends, instead of being eliminated, became encysted without causing any prejudice to the patient. —*Medical Press and Circular*, February 8, 1888.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

TREATMENT OF TYPHOID FEVER.

In an excellent clinic at the Hôpital Necker, in Paris, Prof. Peter recently gave a summary of his views in regard to what he calls typhoid fevers; meaning by this term the different varieties of what is known by the general name of typhoid fever. In this lecture, which is reported in the *Bulletin Médical*, March 25, 1888, Dr. Peter speaks of the change which has taken place in the type of typhoid fever since he first studied it in the days of Chomel and Louis. He rarely sees now, he says, the greatly distended abdomens, the baked tongues, the discharging and excoriated nostrils, the violent delirium and agitation which he formerly saw so often. This fact he attributes partly to the improvement in the hygienic condition of Paris, and the improved sanitary condition of its inhabitants. It is partly due, however, to the modifications which have taken place in the principles governing the treatment of typhoid fever, and the recognition of the fact that its different varieties demand different methods of treatment. He does not commit himself to the microbe theory of the disease or to the theory that it is caused by a ptomaïne or a leucomaïne; he devotes his attention principally to the subject of the fever, and studies what conditions in the latter influence the natural history of the disease, and determine the proper method for conducting the patient safely through it.

His views are so thoroughly in accord with the opinions expressed in an editorial in the REPORTER, December 3, 1887, that we call the attention of our readers to them. Prof. Peter points to the power which the animal organism has to cast out the infecting material which disturbs its functions, and the duty of the physician to abstain from interference so long as this process goes on with reasonable rapidity and success. Bearing this in mind, he warns against any ill-timed effort to restrain the natural attempts at elimination of the poison of typhoid fever, and commends an attitude of expectancy so long as no grave accident of the disease demands active interference.

The conditions which justify non-interference are a reasonably moist tongue, an abdomen in which there is no extreme distension, a skin which is open and naturally moist, and a pulse not much over a hundred. As to temperature, Prof. Peter expresses little concern, and plainly intimates that he does not share the general opinion that its variations indicate the varying gravity of the patient's condition. The line of treatment proper to most cases, he says, is clearly determined by the instinct of the patient: rest is called for by his weariness and exhaustion; diet by his want of appetite; free supplies of water by his thirst; moderate stimulation by his weakness. To meet these instinctive demands, he advises rest in bed, milk food, and lemonade, to which moderate quantities of wine are added. The latter supplies at once three important agents: water, an acid, and a stimulant. Of specific medication he recommends only an occasional saline laxative in the shape of a glass of some aperient water—he says Seidlitz-water, which must not be confounded with the artificial water made with a Seidlitz-powder—and a cool enema, or lavement. Quinine he gives only occa-

sionally, and in small doses, using it solely as a nerve-tonic.

The tenor of Prof. Peter's opinions might be misunderstood, did he not plainly state that he recognizes the fact that there are cases of typhoid fever which demand more energetic treatment; but he states as well that the majority of the cases are amenable to such an expectant method as is outlined above. And he adds that this would be decidedly preferable, as a routine method to the routine application of any of the recognized systematic methods.

The eminence of Prof. Peter as a practitioner and as a teacher and his great experience give unusual weight to his opinions; and those who hold similar opinions may rather be gratified and encouraged than hope to offer any support to them. For this reason we lay his mature and well-digested conclusions before our readers, believing that a careful study of them cannot fail to have a useful influence in guiding any thoughtful medical man to the right way to treat so common a disorder as typhoid fever.

TREATMENT OF PUERPERAL MASTITIS.

In few diseases can more be done, in the way of prevention, than in mastitis. Hence a recognition of its causes is important. Much stress was formerly laid on the influence of draughts of air, mental depression, obstruction of the milk ducts, and so on. The influence of these causes must be remote. Accurate observation has established a frequent causal relation between nipple lesions—ulcers, erosions and fissures—and mastitis. Billroth lays stress upon these lesions, as affording the route of entrance to germs, but he questions the occurrence of infection along the milk ducts. Bumm, who has recently studied the subject, admits both methods of infection, and claims a different course for the affection in each: that infection through surface lesions leads to acute abscess, with only secondary involvement of the lobules, while infection from within the ducts of the glands causes parenchymatous mastitis, beginning as an inflammatory hardening of one or more lobules, and leads to purulent infiltration of the periglandular tissue. As the abscess develops these differential points become confused or lost. Primiparity, and the imperfect establishment of lactation are recognized as factors, and are well known causes of nipple lesions. Prolonged lactation also favors mastitis and abscess. Here debility on the part of the mother, and more especially traumatism inflicted by the infant's teeth, are to be considered. Fordyce Barker and others have called attention to the frequency of mastitis during the prevalence of puerperal septicæmia, distinct from pyæmic abscesses occurring in this situation. Roser pointed out that retention of milk, so long regarded as a cause, is but a result of the process, being brought about by occlusion of some of the excretory ducts from inflammatory swelling. Most obstetricians are now inclined to this view, and regard puerperal mastitis as being in direct relationship to disease of the nipples.

Hence prophylactic measures should be directed toward the preparation of the nipples during pregnancy for lactation, and early recognition and cure of nipple lesions, with the prevention of infection during their course.

The essential element in the successful treatment of mastitis is rest, physiological and physical. Especial attention was called to this by Harris, of New Jersey, in a valuable paper in *Amer. Journ. of Obstetrics*, January, 1885. Nursing from the affected breast should be stopped. The only exception to this rule is in cases of trivial sub-dermal inflammation or abscess; and here lactation should not be allowed if painful. Physical rest is best obtained by the use of the roller bandage. The inflamed breast (or both, if the affection be bi-lateral) should be enveloped in a moderately thick layer of cotton batting, or sheep's wool, and a figure-of-eight bandage firmly, smoothly, and not too tightly applied. The object is to support, immobilize, and slightly compress the breast. A well applied bandage will always give comfort. A roller two and a half or three inches wide and fifteen yards long will be required. The shoulder and axilla may be protected by a

layer of cotton. Wool is to be preferred, owing to its greater resiliency. The bandage may be changed daily, or on alternate days. Other local measures are not called for. Active manipulations, such as stroking, or the use of the breast-pump, should be forbidden; not only because they are founded on a false pathology, but more especially because they add to the mother's pain, and favor suppuration through increased afflux of blood.

By constitutional measures, much can be done to favor resolution and give comfort. The patient should be strictly confined to bed through the active stage. Quinine in doses of from fifteen to twenty-five grains daily, given in two or three doses, unquestionably modifies the inflammation. A brisk purge of the citrate or sulphate of magnesia, given in the beginning and repeated on the second day, relieves vascular tension, and perhaps acts by derivation. Sufficient morphia, or Dover's powder, and the bromides should be given to relieve pain and allay nervous excitement. This treatment, if instituted early, will bring about resolution in a large majority of cases.

When suppuration occurs, the pus should be evacuated early, before it can burrow. Etherization is usually necessary. The incision should be radial, and one-half inch in length. Strict asepsis should be maintained. Where the abscess is large the drainage-tube should be inserted. Insufficient punctures cannot be too strongly condemned. The dressing and after-treatment should be conducted on modern surgical principles, and the process of cicatrization will be greatly assisted by well-applied pressure with the bandage.

PRESCRIPTION OF UNOFFICIAL FORMULÆ.

In connection with our editorial in the REPORTER, April 14, 1888, it is interesting to note that the *St. Louis Drug Clerks' Association* has inaugurated a movement to ascertain what unofficial formulæ, or simple drugs or chemicals, are most frequently ordered by physicians in that section of the country. Circulars have been sent out to a large number of druggists with the request that each recipient shall examine his prescription file for the year 1887, and note what drugs or compounds, not included in the U. S. Pharmacopœia, have been ordered and how often each one of them has been prescribed. The object of this investigation is said to be to furnish information which shall be of use to the Revision Committee of the U. S. Pharmacopœia for 1890. This object is deserving of cordial and general support. It is quite possible that the information intended to assist the Revision Committee in its deliberations may prove quite as interesting to the manufacturers of commercial formulæ as to it; but, none the less, we believe it will serve a useful purpose, if a correct statement can be prepared as to the drugs and compounds which are most frequently prescribed. The general use of any one of these may not certainly indicate its value; but it must suggest the propriety of investigating the causes of its popularity, and if these be found to depend upon intrinsic merit the result cannot fail to be of service to the medical profession.

ANTIPYRINE IN LABOR.

At the meeting of the French Academy of Medicine, March 13, 1888, a paper by Dr. Queirel was read, in which he claimed that antipyrine is a valuable drug in labor, as it calms the excitement of the parturient woman and lessens her pain. Its influence is most beneficial in the first stage of labor; and it does not interfere with its progress at all. Dr. Queirel founds his opinion upon an experience of twenty cases, in fifteen of which his results were very satisfactory. He administers the drug by (hypodermic?) injection, in doses of about four grains, giving a second injection in two hours if the first has not produced the desired effect. Usually he found the influence of the antipyrine to be manifest in from twenty to twenty-five minutes; and he compares it to that of chloroform, with the great advantage that it is a much safer agent.

The announcement of this action of antipyrine tends to confirm the growing opinion that it is an admirable nervine, and supports the views of Germain Seé and of Robin in regard to it.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

THE HYGIENE OF THE SKIN, OR THE ART OF PREVENTING SKIN DISEASES. By A. Ravogli. 8vo, pp. 400. Cincinnati: Central Publishing Company, 1888. Price $3.00.

In the work before us the author has endeavored to collate and present facts bearing upon the etiology of the various skin diseases, and to build upon this foundation proper hygienic measures. After briefly considering the anatomy and the physiology of the skin, the various internal and external predisposing and exciting causes are discussed. Heredity is credited with the most important rôle, as the following clause indicates: "We shall now proceed to consider the hereditary origin of skin diseases, and afterwards show that hygiene may altogether do away with this tendency and prevent their development." A result so desirable would indeed be a boon to humanity; but we regretfully state that a careful reading of the volume fails to add materially, if at all, to our present knowledge. In some respects also the author's statements are not only at variance with predominant medical thought, but erroneous. Thus in the following: "I conclude, therefore, that hereditary syphilis is the ordinary cause of lupus serpiginosus." And also, in speaking of the (early) excision of chancres: "* * * we believe that it is the duty of the physician to try this easy and simple operation, which will not only cure the patient, but will preserve his family from the most disgusting disease that weakens and deteriorates our race." The following remarkable statement in regard to the macular syphiloderm in the hereditary disease may be quoted: "It is never seen on the neck or face."

The illustrations of the anatomy of the skin, and of the parasites, with one or two exceptions, are from Duhring's treatise; and yet, strange to say, these appear without one word of credit as to their source.

OBSTETRIC SYNOPSIS. By John S. Stewart, M.D., Demonstrator of Obstetrics, Medico-Chirurgical College, etc. 12mo, pp. 202. Illustrated. Philadelphia: F. A. Davis, 1888. Price $1.25.

This book, as we are informed in an introductory note by Prof. Wm. A. Stewart, of the Medico-Chirurgical College, is specially intended for the undergraduate student. It has the advantages and disadvantages of its class. The principal aim of the author being condensation, objects other than correctness of statement are necessarily neglected. Under the circumstances, excepting the section on anatomy, the style is all that can be expected. The scientific basis of obstetrics is very lightly dwelt upon, and often does not appear. The sections on treatment are less condensed; but the dogmatic method of statement is used, which appeals to the memory of the student, rather than to his understanding. Among other errors of statement we note the following: The length of the uterus is given as 2½–3 in., which measurements are those of its canal. The utero-sacral ligaments are said to connect the uterus with the sacrum; no mention is made of their insertion as high up as the second lumbar vertebra. Hydræmia is defined as "a general œdema caused by an increase in the watery portion of the blood." Among other obstacles to delivery, hydrothorax, ascites, and retention of urine in the fœtus are cited, and the author then advises that for the removal of retained urine the catheter must be used." We fancy the technique would be difficult under the circumstances.

In so condensed a treatise we would expect omissions; but the evils of condensation are somewhat too manifest in the parts devoted to anatomy and the mechanism of labor. No reference is made to the method of suspension in the treatment of asphyxia neonatorum. Under placenta prævia we find no mention of the wonderful results obtained by the Braxton Hicks' method of delivery. Styptics are given the preference over sutures for the arrest of hemorrhage in lacerations of the cervix and vagina. This is not antiseptic surgery. The routine use of vaginal antiseptic injections is recommended, although at present they are generally abandoned in the normal puerperium. Students are advised to renew the dressing of the umbilical cord daily; which is certainly unnecessary.

The treatment recommended is generally good, and the advice upon the management of labor is sound, especially as to the use of ergot and the delivery of the placenta. The print of the book is excellent, and the text unusually free from typographical errors. With the exceptions indicated above, we think the book calculated to be useful in refreshing the memory of the student, already grounded in the subject, in his preparation for examination.

OPHTHALMIC SURGERY. By Robert Brudenell Carter, F.R.C.S., Ophthalmic Surgeon to St. George's Hospital, etc., and William Adams Frost, F.R.C.S., Assistant Ophthalmic Surgeon to St. George's Hospital, etc. Illustrated with a chromo-lithograph and ninety-one engravings. Small 8vo, pp. 554. Philadelphia: Lea Brothers & Co., (no date). Price, $2.25.

This is an excellently written and well illustrated manual of the important subject of which it treats. The different chapters are signed with the initials of that one of the authors who composed each one, a precaution which seems hardly necessary, as in the preface they state that they are in general agreement with regard to all portions of the volume. The shape of the book is handy, and its moderate price brings it within the reach of all medical men.

TRANSACTIONS OF THE MEDICAL ASSOCIATION OF THE STATE OF MISSOURI AT ITS THIRTIETH ANNUAL SESSION, 1887. 8vo, paper, pp. xi, 159. St. Louis: Ev. E. Carreras, Printer.

The activity of the State Medical Association of Missouri may be indicated by the fact that it has managed to hold thirty annual sessions in twenty-eight years. The volume of Transactions before us indicates that this crowding has not hurt it; but that it has managed to dispose of these two intercalated years without betraying any sign of premature senility. There is so much to attract attention in the papers contained in this volume that we can only call attention to one point: namely, the strong plea of the President, Dr. J. W. Jackson, to bring out the members of the profession who do not take an active part in the proceedings of their State Society, which he introduces by a quotation from a recent address of the President of the State Medical Association of Texas, to which we have already referred in the Reporter, April 7, 1888.

This is a matter which concerns all the States so much that we cannot forbear alluding to it again, in the hope that we may stimulate the desire on the part of all the physicians in the country to share in this means of advancing the good of their fellow-practitioners and of their fellow-citizens.

TRANSACTIONS OF THE MEDICAL AND CHIRURGICAL FACULTY OF THE STATE OF MARYLAND. Eighty-ninth Annual Session, held at Baltimore, Md., April, 1887. 8vo, paper, pp. 152.

One of the most attractive features of this volume —to an editor—is the instruction given, on the page facing the table of contents, to the authors of papers as to the way in which they should prepare their manuscripts. If these were duly studied and diligently observed by all who write for publication, it would save many grey hairs to editors and committees of publication, not to speak of the poor printers themselves. Another interesting feature in this volume is the report of the Publication Committee, from which we learn that the expense of printing five hundred copies of a volume of two hundred and sixty-four pages and five hundred reprints each of the Annual Address and of the President's Address was only $329.18. This is a very good showing indeed, and the committee may be congratulated upon it.

We have not left ourselves much space in which to speak of the papers in this volume, which are not numerous, but interesting and instructive, one of the best of them being the report of a committee appointed to consider the legal points growing out of an address by a former President, Dr. Quinan, in relation to unlicensed practitioners in Maryland. This report may be commended to the attention of medical men of other States, in all of which questions arise similar to those which it discusses.

Pamphlet Notices.

[Any Reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage stamp.]

The Clinical Value of the Cardiograph. By Thomas J. Mays, M.D., Philadelphia. From the *Transactions of the College of Physicians of Philadelphia*, Third Series, Vol. X. 9 pp.

Membranous Enteritis, with Reports of Cases. By William A. Edwards, M.D., Philadelphia. From the *Transactions of the College of Physicians of Philadelphia*, Third Series, Vol. X. 21 pp.

Xeroderma Pigmentosum, and its Relation to Malignant New-Growths of the Skin. By R. W. Taylor, M.D., New York. From the New York *Medical Record*, March 10, 1888. 9 pp.

Pneumonia: its Mortality and Treatment. A Statistical and Rational Inquiry. By Henry Hartshorne, M.D., Philadelphia. From the *Transactions of the College of Physicians of Philadelphia*, February 1, 1888. 35 pp.

—Dr. Mays's paper contains a good description of the instrument called the cardiograph, and of its uses as an instrument of precision in the diagnosis of disorders of the heart and great blood-vessels. It is illustrated with very good woodcuts.

—Dr. Edwards has made a careful and thorough study of the subject of membranous enteritis, especially of cases in which the passage of membrane from the bowels is unaccompanied by the usual symptoms of acute or chronic enteritis or entero-colitis. He describes the symptoms, pathology and treatment of this curious disorder, and concludes his pamphlet with a full bibliographical summary of the literature of the subject.

—Dr. Taylor presents in his paper an account of seven cases of xeroderma pigmentosum which have come under his own observation, and a table of forty cases, which make up the whole number noted in medical literature, including his own. He describes the clinical features of the disease, and lays especial stress upon the frequency with which it is followed by the development of malignant new formations. His paper is accompanied by a handsome plate containing six figures.

—Dr. Hartshorne presents in this paper a strong and scholarly argument in favor of the now almost obsolete practice of venesection in acute pneumonia. He demonstrates by a very complete statistical study that the death ratio in pneumonia is apparently greater now than it was when blood-letting was the accepted method in its treatment, and believes that this fact is not a mere coincidence. There is much in this pamphlet deserving of the consideration of thoughtful medical men, some of which has a direct bearing upon the subject discussed, and some of which suggests interesting questions incidental to it.

Dr. Hartshorne's calculations of the proportion of deaths in cases of pneumonia before and since the abandonment of venesection have been carefully and conscientiously prepared; and the conclusion at which he arrives seems to be justified by his premises. If it is not it would be doing good service for some one who is competent to take the subject up and correct the strong impression which Dr. Hartshorne's paper must produce upon those who read it.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—*Harpers' Young Folks* has been before the reading public for some time, and seems to meet with favor. Its contents are usually interesting and often instructive. But it has one serious defect: namely, that it contains stories and pictures calculated to make a very painful impression upon the minds of the young. Some of these stories and pictures are, in our opinion, so dangerous to the imagination—especially as suggesting horrible dreams—that we think no parent should trust a copy in the hands of his children until he has examined it to see that it is not likely to cause nocturnal terrors.

—*America* is the title of a weekly paper published in Chicago, at ten cents a number and three dollars and a half a year. The first number is dated April 7, 1888, and contains sixteen folio pages. The name of the paper indicates one of its objects: that is, the cultivation of distinctively American ideas. The articles in this number are contributed by some of the best known writers in the United States, and are both interesting and instructive.

Correspondence.

Pyelitis and Purulent Meningitis.

Editor Med. and Surg. Reporter:

Sir:—The following case has proved so interesting to me that I think it may prove interesting to other readers of the Reporter.

Case.—O. H., five years old, had suffered intensely for a year from colic, the nature of which was not fully understood before his death. During the last six months of his life frequent micturitions, with great pain in the lumbar region, led to a suspicion of renal calculi, though no blood was passed, and the pain seemed too constant to be caused by the passage of stones. The patient finally died after an acute illness of two weeks, his disease being diagnosticated as meningitis. One week after his burial, the parents became dissatisfied with the treatment which had been adopted, and were anxious to have the, to them, mysterious case unraveled. To this end they besought the attending physicians, Drs. Rodgers and Baldwin, with my assistance, to exhume the body and make a *post-mortem* examination.

Autopsy.—The brain was unusually large; convolutions well developed, with slight accumulation of fluid in the lateral ventricles. The membranes were congested, fibrinous clot in longitudinal sinus; membrane adhering to the anterior lobe of the left hemisphere; and at the base, especially surrounding the pons, were adhesions, pus and broken-down tissue. The heart and lungs were normal. The liver was normal. The gall-bladder was distended with bile, which had stained the surrounding contiguous parts a dark-green color. The stomach and bowels were normal, except the rectum, which was completely blocked with hardened feces. The kidneys showed pus in both pelves; the capsule of the left kidney was adherent and its tissue friable. The right capsule was not adherent, and the kidney was normal in size; but, lying loose in the pelvis was a stone three-quarters of an inch long, one-eighth of an inch wide, and one-quarter of an inch thick, weighing 18 grains. The infundibula and tubules contained many concretions, varying in size from that of a grain of sand to that of a mustard seed. The bladder was elongated, and when distended held two fluid ounces. Its walls were much thickened and its mucous membrane was sloughing.

Evidently the pain from which the child had suffered was due to the stone; but is there a connection between this and the meningeal trouble of which he died?

He always located his pain in the left side; and the stone was in right. Had it been possible to positively diagnosticate the trouble no operation would have been justifiable, as both kidneys were equally involved.

Yours truly, I. N. Trent, M.D.

Losantville, Ind.,
April 9, 1888.

Notes and Comments.

Early Stages in the Life of Tænia Pectinata.

According to *Science*, March 23, 1888, at the annual meeting of the Women's Anthropological Society, held in Washington, March 8, an interesting account was given of the studies of Mr. Cooper Curtice in regard to the tænia pectinata.

Thousands of sheep and lambs perish every winter on the ranches west of the Missouri river. They are not apparently afflicted with any disease. They are weak and lean in the fall, and simply seem to be unable to withstand the severity of the blizzards. The Bureau of Animal Industry of the Agricultural Department, has been engaged in an investigation to ascertain, if possible, the cause of the weakness of the animals that perish, and Mr. Cooper Curtice visited the West in the prosecution of this work. An examination of the viscera of slaughtered sheep and lambs, fat and healthy ones, as well as those that were weak and lean, disclosed the fact that they were almost without exception infected with tape-worms, which were found in the duodenum and gall-duct. In the latter they were frequently so numerous as to close it up, and cause a suspension of its functions.

For the purpose of continuing his studies, Mr. Curtice brought from the West a number of lambs, which were killed at intervals and their viscera examined; and this material having been exhausted, and it being inconvenient and expensive to obtain more, he turned his attention during the past winter to a study of the early stages in the life of the *tænia pectinata* (common unarmed tape-worms of the rabbit). In studying these, Mr. Curtice thinks that he has made some interesting discoveries, which he presented to the Biological Society of Washington at a recent meeting.

The variety examined is found abundantly in nearly all rabbits in this locality. The life-history of the armed tape-worms of man and dogs has long been written; but that of the unarmed species inhabiting our domestic animals, especially cattle and sheep, is as yet

comparatively unknown. As far as has been ascertained, the life-history of the *tænia pectinata* is embraced in two stages. The first covers the development of the ova into the embryo, which is ready to leave the parent *tænia*: the other covers the period of growth from the youngest forms yet found in rabbits to the adult stage. The life of the *tænia* from the time they leave the first rabbit as an embryo, until they are found as young *tænia* in the second rabbit infected, has as yet been unascertained. Among the theories that have been advanced, is one that they pass this stage upon the ground, are eaten by insects, snails, or crustaceans, and that these are then eaten by the rabbits. This, however, is only a theory, as none have ever been found in snails, insects, or crustaceans.

It was Mr. Curtice's good fortune to find a rabbit which had recently been infected with these peculiar parasites, none of which were over three centimetres in length, many of them being less than five millimetres long.

There were more *tænia* in that rabbit than any he had ever seen before—about eighty-five. Among the smaller *tænia* were several specimens that showed the stages of development from non-segmented, armed forms to segmented, unarmed forms. Mr. Curtice showed to the society specimens illustrating the different stages.

The youngest forms detected were not the smallest, but measured about one-half a centimetre in length. They contained in addition to the four suckers, a cup-shaped cavity, in the place of the rostellum. Around the border of this cup-shaped cavity were situated eighty-five or ninety hooks. The older specimens show a similar cavity, with no hooks. Still older ones show no cavity at all. All of these were in the non-segmented stages; but other forms, some of them smaller, were without signs of hooks, and had already begun segmentation.

Mr. Curtice compared these stages with similar stages in *tænia serata*, and said that the youngest stage of the *tænia pectinata* was probably a cysticercoid stage, and not the cysticercal, and that this was indicated by the cup-shaped cavity in the youngest forms of the *tænia pectinata*.

In discussing the classification founded on the presence or absence of hooks, he declared it to be incorrect, since the discovery described above shows that the unarmed species in adult stages are armed in earlier stages.

The speaker exhibited some elegant drawings made by Dr. George Marx, illustrating the embryo as it leaves the parent *tænia*. This embryo is six-hooked, and surrounded by a curious pyriform envelope, to which there is a double prolongation surmounted by a cap of the same substance. The cap has a shredded border, and is believed to be the remnants of a mass which, in an earlier stage, completely surrounded the embryo. This peculiar envelope has been previously noticed in Italy by Perroucito, and in France by Raillet. This stage is similar to that found in *tænia expansa*, the unarmed tapeworm in sheep.

The Alleged Action of "Médecines a Distance."

A large portion of a recent meeting of the Academy of Medicine of Paris, was devoted to reading the report of the commission appointed to examine into the phenomena related by M. Luys six months ago. It is to be hoped that the report will not only put an end to the mystification of which M. Luys has been the victim, but that it may lead other observers in hypnotism to place somewhat less confidence in the veracity of their subjects. When the experiments were performed by M. Luys, with tubes of which he knew the contents, the results were the same as he had announced to the Academy, the symptoms observed in the patients corresponding to what would be expected from the medicines enclosed; but when the same experiments were repeated under proper test conditions, the contents of the numbered tubes being known neither to himself nor to the members of the commission, M. Luys' subjects failed in every instance to exhibit the proper symptoms. In a word, the conclusion of the whole affair is, that M. Luys has been the dupe of an hysterical patient, and that there is absolutely nothing in all the phenomena so sensationally announced last autumn.—*Lancet*, March 17, 1888.

Composition of Moxie Nerve Food.

Francis Wyatt, says the *Medical World*, has analyzed Moxie with the following result: One hundred parts by weight when distilled were found to contain three-fourths per cent. alcohol, and one-fourth per cent. of the essential oils of sassafras, winter-green and anise. The residuum in the report was evaporated to dryness, and contained 7.880 per cent. of extractive matter, consisting of

Sugar	3.810
Glucose	1.250
Sodium carb	1.070
Sassafras	1.870
Gentian	1.870
Checkerberry	1.870
Quassia amara	1.870

Early Anæsthesia.

There is very little doubt that the Aryan surgeons used some form of local and general anæsthesia. From them came the tendency to use both, which is recorded in early Chinese medical literature. Some traditions of these anæsthetics seem to have been handed down till the time of the Crusades, and to have been revived with the advent of the Renaissance. Boccaccio, for example, says in Decameron, Fourth Day, Novel Ten:—"The physician had a patient who had a bad leg, which was due to a decayed bone. Now, the doctor, supposing that the patient would never be able to bear the pain, ordered a certain water to be distilled that threw a person asleep so long as he judged to be necessary." This practice seems to have died out and become a mere tradition, for Thomas Middleton ("Woman Beware Woman," Act IV, Scene 1, printed in 1657), makes a character say:

"I'll imitate the pities of old surgeons
To this lost limb; who, ere they show their art,
Cast one asleep; then cut the diseased part."

The great revival of anæsthesia which took place late in the first half of the present century, owes its origin to Americans, and there appears no doubt from the results of researches, set on foot by the Chicago Medical Society, that the honor of the discovery of the agent chloroform rightly belongs to Dr. Guthrie, of Sackett's Harbor, N. Y., and not to either Leibig or Soubeiran, who dispute it with him. Chloroform seems to have been used as an anæsthetic in Yale before 1840. Its use was, however, soon discontinued, whether because of the influence of the medical dogmatists who held that pain was salutary, or because of an untoward accident, cannot now be determined.—*Medical Standard*, April, 1888.

The Care of the Nails.

Very few people know how to properly care for the nails. In cleaning them, a sharp knife ought never to be employed, but between the ends of the nails and the fingers the space should be filled with soap, and then removed by brushing with the so-called nail brush. Many improperly cut away that part of the flesh which grows over the nail from the bottom; but it should be simply pressed backward, and sufficiently to show the white part, considered by some to be a mark of beauty. If the flesh is adherent to the nail the operation may be facilitated by passing the sharp point of a knife underneath the fold of flesh and separating it from its attachments. With this done, it can be pushed back more readily. Scissors should never be used to cut the nails; that should be done only with a sharp penknife.—*Boston Journal of Health*, April, 1888.

The Income of Edinburgh Professors.

The Edinburgh correspondent of the *Chemist and Druggist*, March 24, 1888, says that the incomes of the medical professors of the University are notoriously large. Not only is the medical school the most popular and largest attended one in the kingdom, but the chairs are richly endowed. The total income of the chairs in the medical faculty is £26,628 (about $129,150), the expenses in connection therewith, £5,180, (about $25,000), so that a sum of £21,230 ($103,000), remains for division amongst twelve professors. Five of them who do not practice privately as physicians receive each an income of about £2,200 ($10,670), and seven who do practice get about £1,460 ($7,080) each. Some people think that these salaries are too high, and would like a redistribution.

New Dispensary in Washington.

A new dispensary, called the Eastern Dispensary, has recently been opened in Washington City, D. C., for the treatment of the poor of the eastern sections of the city. It is to be entirely free, and no member of the attending staff is allowed to receive pay for services rendered.

The attending staff is composed as follows: *Diseases of the Eye and Ear*, Dr. Thomas A. Taylor; *Diseases of the Throat and Chest*, Dr. F. T. Chamberlin; *Surgery*, Dr. Llewellyn Eliot; *Diseases of Women*, Dr. George Byrd Harrison; *Diseases of Children*, Dr. James F. Hartigan; *General and Nervous Diseases*, Dr. John T. Winter; *Skin Diseases*, Dr. Lachlan Tyler; *Dentistry*, James A. Hunter, D.D.S.

Two new features are the exclusion of cases of gonorrhœa, and that every endeavor, by personal investigation and otherwise, will be made to prevent the admission and treatment of unworthy applicants. The dispensary is to be conducted on a non-collegiate and non-sectarian basis.

—The seventh session of the International Congress of Ophthalmologists will be held at Heidelberg, August 9–12, 1888. Three subjects are to come up for discussion: 1. *Glaucoma:* discussion to be opened by Priestley Smith, of Birmingham; and Snellen, of Utrecht. 2. *Cataract:* Gayet, of Lyons; and Schweigger, of Berlin. 3. *Bacteriology:* Leber, of Göttingen; and Sattler, of Prague.

Accident from Phosphorus.

One of the saddest accidents that has happened among St. Louis pharmacists in a long time was reported in the daily papers of March 6. The victim was Mr. James Reilley, whose place of business was at Fourth and Cedar streets. February 1, Mr. Reilley noticed that a jar of phosphorus was getting dry on the shelf and took it down to remoisten it with water, that being the method druggists have of keeping the drug. The jar exploded, burning the skin off the druggist's hand. Blood poisoning set in in the course of a few days, and the unfortunate man was slowly poisoned. He was only thirty-five years old, and leaves a wife and three young children.—*National Druggist*, March 15, 1888.

Homicidal Insanity in China.

According to the law of China, the punishment inflicted on the murderer of a father, mother, brother, husband, uncle, or tutor, and on traitors, is that appalling process known as *ling-chie*, or slow death. The fact that the crime has been committed under the influence of insanity procures no mitigation of the dread sentence, and the miserable culprit is sentenced to be cut into 24, 36, 72, or 120 pieces, a large proportion of which must be accomplished ere the executioner dares to touch a vital part, and end the torture of the victim. Only in certain cases does the Imperial clemency grant death after the eighth division. The commonest form of this penalty is that of twenty-four cuts; and the executioner prides himself on the anatomical skill with which they are administered. The victim being bound to a cross, the butcher by the first two cuts removes the eyebrows, by the third and fourth the shoulders, the fifth and sixth the breasts, the seventh and eighth the flesh of the forearm, the ninth and tenth the flesh of the arm, the eleventh and twelfth the flesh of each thigh, and so on.—*British Medical Journal*, Jan. 21, 1888.

Caffeine.

M. M. Paul and Y. Cowley have succeeded in determining the influence exercised by the process of roasting upon the proportion of caffeine contained in different kinds of coffee. Dry coffee contains from 1.1 to 1.18 per cent. of caffeine. If the roasting is effected at a moderate heat, the loss of caffeine is trifling; but if it be, on the contrary, carried to a high temperature, the quantity of caffeine does not amount to more than 0.36 per cent.

Formula in Dysmenorrhœa.

The following is recommended by Goubert (*Am. Journal Med. Sciences*, April, 1888):

Iodoform.....2 grains
Ext. of belladonna.....½ grain
Asafetida.....4 grains

M. ft. pil. No. j. Six of these pills are given daily, and from six to ten days before the appearance of menstruation.

American Association of Genito-Urinary Surgeons.

A preliminary programme for the meeting of the American Association of Genito-Urinary Surgeons, to be held in Washington, D. C., September 18, 19 and 20, 1888, has been issued by the Secretary, Dr. R. W. Taylor, of New York. The programme announces the following papers:

Clinical Observations on Diseases of the Testicle. By *Dr. L. B. Bangs*, of New York.

Clinical Observations on Gonorrhœa, and two cases of Cancer of the Seminal Vesicles, with Pathological Specimens. By *Dr. J. P. Bryson*, of St. Louis.

Operative Treatment of Hypertrophy of the Prostate, and Case of Bowel ending in the Urethra of a Child four weeks old; Relief by Operation. By *Dr. A. T. Cabot*, of Boston.

On the Effects of Rapid Changes of Altitude in an Advanced Case of Interstitial Nephritis. By *Dr. George Chismore*, of San Francisco.

Connection between Masturbation and Stricture. By *Dr. S. W. Gross*, of Philadelphia.

Operations on the Kidney. By *Dr. W. H. Hingston*, of Montreal.

Syphiloma of the Vulva. By *Dr. J. N. Hyde*, of Chicago.

The Curability of Urethral Stricture by Electricity; an Investigation; and the Comparative Value of Supra-pubic and Perineal Drainage in Curable and Incurable Bladder Disease. By *Dr. E. L. Keyes*, of New York.

The Filaria Sanguinis Hominis in the United States, especially in its Relationship to Chylocele of the Tunica Vaginalis Testis. By *Dr. W. M. Mastin*, of Mobile.

A Case of Perineal Section for Traumatic Retention; Unusual Condition of the Bladder. By *Dr. J. E. Michael*, of Baltimore.

The Prophylaxis of Syphilis. By *Dr. P. A. Morrow*, of New York.

Unusual Case of Urethral Calculus. By *Dr. H. G. Mudd*, of St. Louis.

On the Radical Cure of Stricture by Dilating Urethrotomy; and Demonstration of a Per-

fected Evacuator, and an Improvement in the Method of Removal of Debris from the Bladder. By *Dr. F. N. Otis*, of New York.

Pyæmia as a Direct Sequel of Gonorrhœa. By *Dr. R. Park*, of Buffalo.

Retrojections in Gonorrhœa. By *Dr. E. R. Palmer*, of Louisville.

Prostatotomy for Enlarged Prostate at the Age of Forty-two. By *Dr. Abner Post*, of Boston.

A Case of Removal of both Testicles for Recurrent Carcinoma, and A Case of Nephrolithiasis Complicated with Hydronephrosis, in which Lumbar Nephrotomy was Performed. By *Dr. F. W. Rockwell*, of Brooklyn.

Some Points on the Differential Diagnosis of Bladder and Kidney Affections, with Demonstrations of the Cystoscope and Other Instruments; and On the Physiology of the Bladder. By *Dr. Alexander W. Stein*, of New York.

Local Treatment of Chronic Urethral Discharges. By *Dr. F. R. Sturgis*, of New York.

Some Points on the Etiology of Stricture of the Urethra. By *Dr. R. W. Taylor*, of New York.

Operative Treatment of Hypertrophy of the Prostate; Spontaneous Fracture of Stone in the Bladder. By *Dr. F. S. Watson*, of Boston.

The Relation of the Prostate to Chronic Urethral Discharges; and The Value of the Tolerance of the Iodides as a Diagnostic of Syphilis; and Urethral Stricture and Enlarged Prostate in their Relation to Vesical Calculus and Calculus Pyelitis, with cases. By *Dr. J. William White*, of Philadelphia.

BY INVITED GUESTS.

The Prognosis of Stricture, based on thirty years' death record of Stricture at the London Hospital and the Practice at St. Peter's Hospital. By *F. Hurry Fenwick*, of London.

The Congenital Anomalies of the Exter nal Urethral Orifice. By *Dr. C. Kaufmann*, of Zurich, Switzerland.

Small-pox in Philadelphia.

A few cases of small-pox have appeared in Philadelphia within the past two weeks. The Health Officers do not think there is any danger that the disease will extend; but a great impetus has been given to vaccination.

Death of Dr. Loring.

Dr. Edward G. Loring, the distinguished specialist in diseases of the eye, dropped dead on the street in New York, April 23, 1888.

Trichinosis in Indiana.

It is reported from Richmond, Ind., under date of April 13, that a whole family in Ridgeville, Randolph county, was suffering with trichinosis. Dr. Helms was called to attend the patients, and discovered the presence of trichinæ in a ham which they had been using for food.

Pennsylvania State Sanitary Convention.

A Sanitary Convention under the auspices of the State Board of Health of Pennsylvania is to be held in Lewisburg, on May 17 and 18, 1888. Governor Beaver is to make the opening address, and Hon. S. T. Davis, M.D., of Lancaster, the annual address. Papers are promised on The Prevention of Contagious Ophthalmia, by Dr. P. N. K. Schwenk, of Philadelphia; on Diseased Meats and the Prevention of Trichinosis, by Dr. G. W. Furey, Sunbury, Pa.; on The Water Supply of Lewisburg, by Prof. W. G. Owens, Bucknell University; annual address, Hon. S. T. Davis, M.D., Lancaster, Pa.; on Cremation as a Means of Disposal of the Dead, by Dr. B. F. Hyatt, Lewisburg, Pa.; on Small-pox in Country Places, by Dr. Fetterolf, Mazeppa, Pa.; on Hygiene of the Teeth, Dr. F. Gerhart, Lewisburg, Pa.; on Insanity Among Women, Alice Bennett, M.D., Resident Physician State Hospital for the Insane, Norristown, Pa.; on Sanitary Protective Associations, by Benjamin Lee, M.D., Secretary of the State Board of Health; on Sanitary Shortcomings of Lewisburg, by Dr. W. B. Atkinson, Secretary of Pennsylvania State Medical Society, and Medical Inspector of the State Board of Health; on School Hygiene, by Dr. G. G. Groff, of Lewisburg, member of the State Board of Health; on Household Hygiene, by Dr. Francis Emery White, of the Woman's Medical College, Philadelphia, Pa.; on How Germs Cause Disease, by Dr. V. C. Vaughan, of Michigan University; on The Drainage of Lewisburg, by M. S. D. Bates, Lewisburg, Pa.

The aim of the meeting will be to make the paper of practical use to the citizens of Lewisburg and its neighbors, and to enlist them in the study of its sanitary problems. For this reason they will be of great interest to all residents in small towns and rural districts, the conditions of which are necessarily very similar.

NEWS.

—Dr. R. P. Brochin, editor of the *Gazette des Hôpitaux*, died in Paris, March 25.

—Dr. C. P. Wilkinson has been elected President of the Louisiana State Board of Health.

—A bill incorporating an institute for teaching "Christian Science" has passed the Legislature of New York.

—Professor Wilhelm Leube, of Würzburg, has been appointed to the Professorship of Clinical Medicine at Leipsic.

—The telegraphic reports of the condition of the Emperor of Germany indicate an alarming change for the worse.

—Dr. Hermann Krause, *privat-docent* in laryngology at Berlin, has been granted by the Emperor the right to the title of Professor.

—The Medical Department of the Western Reserve University has decided to lengthen its course to three years, beginning next fall.

—Dr. Thomas Keith, the distinguished gynecologist, has resigned his position in the Edinburgh Royal Infirmary, and removed to London.

—Dr. George M. Sternberg, U. S. A., who was last year commissioned by the President of the United States to study in Brazil the protective value of inoculation in yellow fever, presented to the College of Physicians of Philadelphia the results of his researches in an interesting address on Saturday evening, April 21.

—Dr. Anna Kingsford, who recently died in London, believed that she was the reembodied spirit of Lady Jane Gray. She visited the Tower of London one day, in the body of Dr. Kingsford, and became acquainted with herself, as it were. Dr. Kingsford was a very brilliant woman and learned languages and history with wonderful ease.

—The *Sacramento Medical Times*, April, 1888, says that small-pox is evidently subsiding in every part of California from which it had been reported, excepting Angels, Murphys and San Andreas, in Calaveras county, where it appears to have been mistaken for chicken-pox, and where it has consequently obtained a foothold sufficient to necessitate the intervention of the State Board of Health. All of the cases, however, being now quarantined, and thorough and systematic vaccination having been inaugurated, it is not doubted but it will be confined to the few persons already attacked. The cases are also reported to be of a mild type, as are also the few which are still occasionally reported from San Francisco and other localities.

HUMOR.

His Own Diagnosis.—Mother—And do you really feel so very bad, Bobby? Bobby—Yes, ma. I ain't quite sick enough to need any medicine, but I'm a little bit too sick to go to school.

Bobby—Ma, did the doctor bring me in the day-time or night-time? Mother—In the night-time, Bobby. Bobby—Well, I guess that's the reason I don't remember anything about it; I must have been asleep. —*Harper's Bazaar.*

"Well, how is this, my dear sir?" inquired the local practitioner; "you sent me a letter stating that you had been attacked by small-pox, and I find you suffering from rheumatism." "Well, you see, doctor, it's like this," said the patient; "there wasn't a soul in the house who could spell rheumatism."

A Wise Mother.—Aunt: "Can you get your cod-liver oil down, my child?" Little patient: "It tastes horrible; but mamma gives me five cents every time for my savings-bank." Aunt: "And, what do you do with the money, my dear?" Little patient: "Oh, mamma buys cod-liver oil with it."—*Fliegende Blätter.*

Those Cruel Medical Students.—(Dr. Carver has disappointed his quiz class to dine with a wealthy patient.)—Butler (reappearing after answering the front-door bell)—"Doctor, dey's a gemplemum outside what say he come like you tole him call at harf-pas' seving, an' say Mrs. Lenox Hill wan' to see you right 'way!"—*Puck.*

"I haven't had no lesson since yesterday," pouted Johnny. "That means you have had a lesson," said the teacher. "Who remembers what I said this morning about two negatives in a sentence?" "I do, I do," yelled the smart boy on the front seat. "You said two negatives made one infirmity."—*Texas Siftings.*

Convalescent (to physician)—I see your bill, doctor, calls for $10. How much do you charge a visit? Physician—Two dollars. Convalescent—But you only called three times. Physician—Five times, my friend, three times for treatment and twice for my money. Convalescent—I guess I had better hurry and pay up.—*The Epoch.*

A Georgia negro, having hurt his leg, treated the wound with mud from the Ocala swamp, and found when he removed the bandage that the wound was healed and that the leg had turned almost white. The result is that the negroes of the vicinity are flock-

ing to the swamp and covering themselves with the mud, hoping it will turn them white.

A SMALL BOY of Springfield, Mass., went to the grocery to get some things for his mother, but when he tried to recall one of the articles he couldn't think of the name. He said it was yellow, and in various ways tried to give the clerk an idea of what he wanted, and finally in desperation blurted out: "Why, you know what I mean—that stuff that they burn in hell!" Then the clerk got him the sulphur that he wanted, and the orthodox child went home happy.

OBITUARY.

CORNELIUS R. AGNEW, M.D.

The many friends of Dr. Cornelius R. Agnew, of New York, have been pained by his death after an attack of perityphlitis, for which the operation of laparotomy was performed on April 13, by Dr. Sands. For a short time the operation gave him relief, but it failed to save his life, and on April 18 he died. Dr. Agnew was born in New York in 1830. The family settled first in Philadelphia and afterwards removed to New York. He studied at Columbia College, New York, graduating in 1849, and then studied medicine in the New York College of Physicians and Surgeons. He graduated in medicine in 1852, and in the following year became House Surgeon in the New York Hospital. Soon after he went to Europe and studied in Dublin, London and Paris for two years. Returning to America in 1855, he established himself in New York as a general practitioner, and until 1864 was surgeon in the Ear and Eye Infirmary. In 1858 he was appointed Surgeon-General of the State of New York by Governor E. D. Morgan, and at the commencement of the Civil War the same Governor appointed him Medical Director of the State Volunteer Hospitals of New York, a position of great trust. When the famous Sanitary Commission was organized Dr. Elisha Harris and Dr. Cornelius R. Agnew were unanimously elected as colleagues, and it is explicitly stated in Dr. Charles J. Stillé's history of the Commission that the success of that enterprise was very largely owing to Dr. Agnew's labors. Dr. Agnew was one of the surgeons who prepared the plans for the "pavilion hospital system" generally followed during the war.

AZARIAH LYCURGUS KIMBRO, M.D.

Dr. Azariah L. Kimbro died in Memphis, Tenn., March 17, 1888. He was sixty-two years old at the time of his death. He was graduated from the Botanic Medical College, of Cincinnati, Ohio, in 1846, and subsequently practiced medicine in Franklin, Tenn., until 1848, when he removed to Memphis. He leaves a wife but no children.

D. JEROME SANDS, M.D.

Dr. D. Jerome Sands, of Port Chester, New York, died February 29, of pneumonia He was seventy three years old, was graduated from the College of Physicians and Surgeons, New York, in 1840, and leaves a son who is a physician.

ALBERT G. BROWNING, M.D.

Dr. Albert G. Browning, of Providence, R. I., died of apoplexy, April 5. He was graduated from the Medical Department of Yale College in 1863, and for nearly 25 years practiced medicine in Providence, being highly esteemed for his skill and integrity.

Changes in the Medical Corps of the U. S. Navy for the week ending April 21, 1888:

Medical Inspector A. C. Rhoads, detached from special duty New York, and waiting orders.

Passed Assistant Surgeon L. G. Henneberger, detached from Naval Hospital, New York, and to special duty attending officers and families, New York.

Official list of changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from April 15, 1888, to April 21, 1888:

Major George M Sternberg, Surgeon, having been instructed by the President to proceed to the island of Cuba, for the purpose of continuing his investigations of the methods of preventing the spread of epidemic diseases, will, in connection with his present duties, report to the Secretary of the Treasury for further instructions, S. O. 89, A. G. O., April 18, 1888.

Capt. Clarence Ewen, Assistant Surgeon, granted leave of absence for six months, with permission to go beyond sea. S. O. 85, A. G. O., April 13, 1888.

Capt. William H. Arthur, Assistant Surgeon, ordered from Fort Niagara, N. Y., to Fort Bowie, Ariz., to take effect on the expiration of his present leave of absence.

First Lieutenant Charles S. Black, Assistant Surgeon, ordered from Fort Davis, Tex., to Fort Sidney, Neb. S. O. 86, A. G. O., April 14, 1888.

The operation of par. 17, S. O. 79 c. s., A. G. O., (as much thereof as relates to Capt. Geo. E. Bushnell, Assistant Surgeon, U. S. Army), is suspended until May 1, 1888. S. O. 90, A. G. O., April 19, 1888.

First Lieutenant Wm. D. Crosby, Assistant Surgeon, ordered for duty at Jefferson Barracks, Mo., after being relieved by Assistant Surgeon William H. Arthur, and upon the expiration of the leave of absence granted him in S. O. 60, A. G. O, March 14, 1888. S. O. 86, A. G. O., April 14, 1888.

Appointment.

Ogden Rafferty, to be Assistant Surgeon with rank of First Lieutenant, March 26, 1888.

Promotion.

Captain Joseph B. Girard, Assistant Surgeon, to be Surgeon, with the rank of Major, March 22, 1888.

WHOLE No. 1627.] MAY 5, 1888. [VOL. LVIII, No. 18.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

SOMETHING NEW.

ELIXIR OF COCA AND CALISAYA

which represents the virtues of these drugs in a *most active and palatable form.* The process of manufacture is ENTIRELY ORIGINAL—that of direct fermentation from the bark and leaf—and we claim that better results can be obtained from this preparation than from any other combination of *Coca and Calisaya* now made.

MADE ONLY BY

Clinical Lecture.

ON FRACTURE OF THE LOWER END OF THE HUMERUS.

BY J. S. WIGHT, M.D.,
PROFESSOR OF OPERATIVE AND CLINICAL SURGERY AT THE LONG ISLAND COLLEGE HOSPITAL.

Gentlemen:—This boy is eight years of age. Two weeks ago he fell on his left elbow and broke the lower end of the humerus. His injured limb has been supported by a posterior splint, so that the forearm has been about midway between a right angle and complete extension. You may know that such a case is important, when I tell you that its diagnosis is uncertain, that it is difficult to treat, and that the results cannot always be known beforehand.

When such an injury occurs, and is presented for your examination and treatment, you have two standards for your guidance. First: In your general study of anatomy, you have formed and carry with you some ideal of the structure and uses of the elbow-joint. With this more or less correct ideal you compare the injured limb, and make a note of the signs. Second: You carefully examine all the land-marks of the other elbow. This is your best standard of comparison. Keep one hand on the normal elbow, and the other on the one that has been injured. At each and every point contrast and compare the injured with the normal structure. An analysis of your impressions will give you additional facts, which will aid you in your diagnosis. Then see how much the motions of the forearm on the injured side have deviated, and try to determine the causes that have impaired these motions. Is there a fracture of the bones at the elbow? Has the elbow-joint been sprained? And what is of the greatest importance, we should always ask if the injured part has suffered injury or disease at some previous time. We may not mistake the results of an old injury for the effects of one that is recent. An injury to a diseased joint brings two conditions to our attention: how much of the disorder was caused by the disease; how much of the damage was produced by the injury.

Let us begin our examination by noting the land-marks of the uninjured elbow. The head of the radius and the external condyle are formed to project equally on the outside; one is as prominent as the other. I have very rarely seen an exception to this rule of conformation. The ulna appears to be on a line with the humerus, just as if it were the prolongation of that bone. And the curve of the radius and the expansion of the radial base cause the forearm to meet the arm at an obtuse angle. The internal condyle is prominent, as well as the olecranon process of the ulna. Mark the groove between these two processes, and keep in mind the distance of one from the other. See the way in which the olecranon moves to and fro during extension and flexion of the forearm. Remember that at the age of our patient the lateral motion of the forearm, so common in early life, has mostly disappeared. In our patient this evanescent function is absent. In fine, the motions of flexion, extension and rotation of the forearm of the uninjured limb are practically normal.

I have already told you that this boy had broken the lower end of his left humerus: I expect to prove this conclusion beyond the possibility of a doubt. But in the mean time let me say to you, that the changes taking place in the lower end of the humerus, as it develops, have important bearings on the causation, nature, treatment, and the results of fractures, such as we have illus-

trated by the case of our patient. I allude to the epiphysis and the cartilage between it and the diaphysis. In our patient ossification is going on in the end of the humerus adjacent to the radius, the external part of the ulna, and the internal condyle. And it seems to me that this change from cartilage to bone, which occurs in the ends of long bones, is sometimes a reason why a fracture happens so often in this location. In making this statement I do not underestimate the influence of other causes. But I am inclined to the opinion that this ossifying cartilage, though the change goes on very slowly, resembles provisional callus; for both are apt to yield and even break under the impact of external violence. The bearing of this ossifying structure on the nature, treatment and results of such fractures will receive our attention, when we have made our diagnosis.

Let us inspect this injured limb and see what we can find. The condyloid end of the left is greater in width than the corresponding end of the right humerus. Measurements by the calipers show that the lower end of the right humerus is about an inch and three-fourths in width, and that the lower end of the left humerus is about two inches in width, demonstrating the fact that the injured elbow, from some cause, has been made wider than the other. The forearm of the injured limb bends and falls to the inner side. The external angle usually made by the forearm and the arm at the elbow-joint is obliterated, and an internal angle is formed. The entire forearm is displaced inward nearly one-fourth of an inch. Observe this somewhat sharp prominence just above the place where we ought to find the head of the radius. You can see that the head of the radius is displaced inward, and part of the radial head of the humerus has gone along with it, leaving a rough end of broken bone under the skin and fascia. This rough end can be seen, and can be distinctly felt. How can the upper end of the radius move inward and not take the upper end of the ulna along? And we find that the ulna has moved inward about one-fourth of an inch. But, as you see, the internal condyle has also moved inward. And if we measure, we shall find that the internal condyle and the upper end of the ulna have nearly the same relations on the injured as they have on the normal side; the apex of the internal condyle is about as far from the olecranon on one side as on the other. And we discover a deeper curve on the inner aspect of the left arm just above the elbow than in the same location on the right arm. It seems as if the more internal parts of the left humerus, near the internal condyle, had been bent inward, without giving way entirely, producing a form of incomplete fracture. The age of our patient would be in favor of such a conclusion.

Now we may consider the displacements of the fragments, for we may assume that the lower end of the humerus has been broken. The head of the radius and the radial head of the humerus are, as you can see, displaced backward somewhat further than the upper end of the ulna, the trochlea and the internal condyle. The lower articular end of the humerus is displaced inward about one-fourth of an inch. This lateral displacement is as great as the shortening of the injured humerus. It seems that the lower end of the upper fragment is displaced outward and somewhat forward about one-fourth of an inch.

The motions of the elbow-joint are impaired. The forearm can be moved to a point about twenty degrees from complete extension, and from thence nearly to a right angle with the arm. It has lost more than one-half of the function of flexion and extension. The left forearm has about thirty degrees less rotation than the right. Its lateral motion has been somewhat augmented. These motions are passive. They are made by the surgeon. The voluntary motions of this elbow-joint are very much impaired, not only on account of the mechanical obstructions, but also on account of the pain and the tenderness. In fact, the motions are not all confined to the joint. There is mobility in the continuity of the lower end of the humerus. The radial head of the humerus is broken off obliquely inward and upward, and there is a line of separation between it and the trochlea, so that the motion of the fragment is added to the motion of the elbow-joint. The simple fact is that the head of the radius has left its normal relation with the external condyle. The fracture extends obliquely upward and inward from the fragment just described, displacing inward the internal condyle, which is not completely detached from the shaft of the humerus, and yet the separation is sufficient to add some mobility to the elbow-joint.

In this place let me call your attention to the nature of some fractures that occur in the condyloid end of the humerus, and to the position of the forearm in the case of this patient. I have seen a number of cases of incomplete fracture in the ossifying cartilage of the condyloid end of the humerus. These cases have occurred in boys from six to fifteen years of age. In the case of this

boy the fracture is mostly complete. The lower end of the diaphysis of the humerus is split upward and inward, and the fibres of the bone on the internal aspect above the internal condyle are partly broken and partly bent. It seems as if the olecranon had acted as a wedge to penetrate to some extent the intercondyloid tissue, and aid in no small degree the displacing effects of the external violence that was applied at the time of the fall. I think that there can be no doubt of the existence of a fracture of the lower end of the humerus in this case. It is complete on the outside, and it is incomplete on the inside of the humerus.

Let me say to you that from time to time I have seen incomplete fractures, that have occurred in the ossifying cartilage of the lower end of the humerus. These fractures traverse the tissue vertically, obliquely and transversely. They are most apt to occur in boys, between the ages of six and fourteen years. The structure seems to split for a certain distance, and form a wedge-shaped opening, which is usually filled up by the material of repair. The displaced fragments, are, for the most part, irreducible. Had we the time at our disposal, I could give you the clinical history of a number of these cases coming under my observation and treatment.

Let me give you a few words in regard to the position of the forearm in the case before us. Since the ulna is attached to the inner fragment, and since that fragment is bent inward, and since the radius is attached to the outer fragment, and since that fragment is displaced backward, it follows that the entire forearm is rotated outward to some extent. This is one of the displacements of the forearm, which has followed the lower fragment of the humerus in its internal angular displacement. Let me call your attention to some points of scientific and practical importance in regard to the attitude of the forearm. The space between the ulna and radius is greatest when the forearm is in a position of mid-rotation, and the radius approaches the ulna from this position to complete pronation, as well as to complete supination. And when the forearm is flexed to a right angle with the arm, carried across the chest, and kept vertical, so that the radius is directly over the ulna, the bones of the forearm will be in the same plane, and will be at their greatest distance from each other. This plane of the forearm, as you see, meets the long axis of the arm at an acute angle that differs as to size in different patients. Now I have often given you reasons why the forearm as a rule ought to be put in this position during the treatment of fractures in the vicinity of the elbow-joint. This position tends not only to equalize the antagonism of the muscles that span the elbow-joint, but it also conduces to the reduction of the displaced fragments of bone. And if we construct a splint on the mechanical principles suggested by the conformation, the structure and the muscular apparatus of the elbow and its relations, it will accomplish two important indications: we can make a more complete reduction of the displaced fragments, and the patient will have the greatest relief from pain. I have proved these two propositions in a practical way on many occasions. More than once I have been surprised at the completeness of the reductions of the bony fragments, as well as their retention in position during the process of repair. Often patients have expressed relief from pain, when this form of splint has been applied.

This apparatus would appear to be an unnecessary refinement—and so I have been told. In reply to this, let me say, that the surgeon is morally bound to give his patient as much freedom from pain as he can. He is bound by the same kind of obligation to apply his best skill in the treatment of the case. He must reduce the fragments in so far as it can be done safely. He must put in practice those principles which will, according to his best judgment, restore and conserve the functions of the damaged structure to an extent which will be consistent with ordinary skill; and he may go as far beyond that as he can. The ambition of the surgeon ought to lead him in the direction of the highest success. Now in my hands this splint, having two angles as above described, has accomplished good results. In fact it has answered a better purpose than any other that I have employed; and so I recommend it.

You will see that the motions of this elbow-joint are very much impaired. And then you ask—what is the cause? Let me explain: The joint surfaces which fitted and moved in opposition before the injury, have been deformed, so that the parts have lost their adjustment, and so that the projecting points of bone on both sides of the joint meet and obstruct each other. And since the fragments have been only imperfectly reduced, the obstructions to the motions of the joint must continue to operate. But the case does not remain in this condition. The process of repair has furnished new material between and around the fragments, so that the obstructions to motion have been augmented. In fact, the process of repair works in the

direction of making the fragments grow together, and does not seem to have any special purpose in restoring the motions of the joint. In addition to this, bands of adhesion, as they are called, attach one part to another so as to further impede the motions which have been impaired.

And then there is another point connected with this injury: I mean that there has been some damage done to the neuro-muscular apparatus. In a healthy joint which has not been injured there is a coordinate relation between the nerves and muscles concerned in the motions of that joint; and the bony levers are involved in this relation. That is, we have a triple relation of bones, muscles and nerves. Damage to either factor will derange the entire coordinate relation so as to interfere with the performance of function. The bony supports, as points of resistence and surfaces of motion, have been seriously damaged in this case. The nerves have been injured and irritated. The nerves send messages to the muscles, not to make them keep quiet, but to cause them to contract, and they do so without discretion. The fulcrum of the bones of the forearm is in pieces and can not normally sustain the force of the contracting muscles that span the elbow-joint. Now the muscles not only displace the fragments by traction on the bones, but they will also in time become shortened; they will become *contractured.* And then, as you now see, we have another reason why such an injury, as the one before us, impairs the functions of the part in which this triple relation of bone, nerve and muscle has been deranged.

Let me tell you another thing which sometimes leads to a difference of opinion among surgeons, and is apt to be a cause of controversy. I mean this: That these cases of injury to the elbow-joint, accompanied by fracture of the condyles of the humerus, eventuate in very different results in different cases. It is the old story, which we are all so slow to learn, which begins in the constitutional condition of our patients who are not all put together with the same physical consistency. One patient will have a trivial injury to the elbow, and be left with the functions of the parts greatly impaired. Another will have a severe injury, even involving a compound fracture of the condyles of the humerus, and have a recovery that is almost perfect. Both of these cases may be treated on the same plan and with the same degree of skill; even the one that has resulted with the greatest disability may have been treated with greater care and skill than the other. The difficulty does not exist in the treatment, but comes out of the physical condition of the patient. Hence it has occurred that one surgeon has had a series of cases of fractures of the condyles of the humerus, in which good results have supervened, and then he extols the plan of treatment that he has pursued; and perhaps he may come to the conclusion that he can always prevent disability in cases of fracture of the elbow. I need not emphasize the fact that this surgeon is mistaken. On the other hand, another surgeon may have had a series of these cases of fracture, and may have had them all in the main result in more or less disability. Let him not be discouraged for he may have treated his cases with more than ordinary skill. The results may have been due to the intrinsic difficulties of the cases, which no one can overcome. Let surgeons reason together; let no one be discouraged; let no one be unduly exalted. It is easier to criticize work than it is to perform it; and the apparent results are not always the index and the measure of the skill that has brought them about.

There is one point connected with fractures in the vicinity of joints in regard to which you may be in some doubt. This point relates to passive motion. On passive motion there are many different opinions among surgeons. One says, begin passive motion soon after a fracture occurs; another says, institute passive motion at the end of three or four weeks; and still another says, make passive motion when six or eight days have elapsed. Again, one surgeon says, make passive motion every other day; a second says, make passive motion every third or fourth day; and a third says, make passive motion about once a week. Each one of these precepts has given good as well as bad results; and this means that the methods are not so much at fault as the condition of the patient and the circumstances of the case. Your difficulty, when there is so much uncertainty, will be to know what to do in a case of fracture of the elbow, for instance.

In the light of experience, let us analyze this subject of passive motion. What is the object of passive motion? Practically, it is to prevent, as far as possible, the impairment of voluntary motion. When the fragments have grown together, it is desirable not to have a disabled joint in the vicinity of the fracture. What events are apt to occur in the vicinity of the elbow-joint, when there is a fracture of the condyles of the humerus? The inflammation, incident to the process of repair, may implicate the

tendons and their sheaths, as they span the joint, and leave adhesions that may interfere with voluntary motion. Also the inflammation may agglutinate the various forms of connective tissue about the joint, so as to aid in the production of disability. The new material that is formed for the repair of the broken bone, as we have indicated, will be a potential cause of anchylosis. Now what will be the effect of passive motion on the formation of adhesions between the layers of connective tissue as well as between the tendons and their sheaths? Passive motion of proper kind and degree, in the great majority of cases, will be instrumental in preventing, or limiting the formation of such adhesions. Sound theory, as well as abundant experience, has corroborated this conclusion. Severe injury and excessive inflammation might interfere for a time with our attempts to make passive motion. In the next place, would passive motion interfere with the formation of callus? and would it cause the displacement of the fragments? In a case of incomplete fracture, or when the fragments could not be reduced, passive motion would not cause displacements. In any other case, except when there is great swelling of the soft parts, it is possible, as a rule, for the surgeon to hold the fragments in place as he makes careful passive motion. I have often verified this practice. In regard to the new material that is going to be transformed into bone: in general, the pressure produced by the passive motion will make the new ossifying material yield and cause it to be absorbed, so that the bones of the forearm can be flexed and extended more and more, thus conducing to a better result.

Now, what kind of passive motion shall we make in these cases? Let it be gentle, so as to prevent adhesions between the tendons and their sheaths, and so as to keep the new ossifying material from obstructing too greatly the motions of the joint. As a rule, let passive motion begin from three to five days after the fracture has occurred, and let it be repeated every three or four days from that time till treatment is no longer required. There is no fixed time for treatment to continue; one case may need passive motion only a few weeks, and another may need it as many months. Let me illustrate: One boy, about nine years of age, broke the condyles of his left humerus, and in six or seven weeks had good union, with nearly perfect restoration of the motions of the forearm. This case was treated on the plan above described. Another boy, about fourteen years of age, broke the condyles of his right humerus, and, after ten months of the most persistent and careful treatment, had firm union of the fragments, but could flex and extend the forearm only about one-half the normal distance. The constant tendency in this case was to anchylosis. On several occasions I administered ether and broke up the adhesions, causing some absorption of the new bone, so as to augment the extent of the motion.

One of the possible sequences of passive motion must be mentioned. There may be fibrous union between the fragments of bone, leaving a new point of motion, with the joint more or less impaired. This condition may not augment the deformity to any great extent, and it will not very greatly diminish the strength of the joint, while it may increase the motions of the forearm. Now, it might be that motion of the forearm would be more desirable than resistance of the elbow-joint, so that fibrous union of the bony fragments might be more useful than anchylosis. And let me add that I have seen fibrous union take place when the case has been treated without passive motion. Also, I have seen the condyloid fragments mostly absorbed, so that the motions of the forearm have been very much greater than normal. Furthermore, I have seen two sets of cases: one in which the forearm could not be flexed above a right angle, not only on account of the projection of the lower end of the upper fragment, but also on account of the formation of new substance in front of the elbow-joint, but the extension of the forearm has not been greatly limited in such a case. The other set of cases has exhibited a persistent tendency to flexion of the forearm even above a right angle, and has presented such obstruction to extension as has been very difficult to overcome. The difficulty in such a case appears to depend on resistance to the olecranon by new substances formed in the olecranon fossa, as well as on contracture of the flexors that span the elbow-joint.

—Dr. Cullimore asserts (*British Medical Journal*) that 10 drops of a fluid extract of phytolacca decandra, repeated a few times, aborts inflammation in mastitis. The drug acts as a general narcotic, but only in a favorable way. In larger doses it excites vomiting and diarrhœa, which may be followed by coma and death. It may also be used externally directly to the breast, or in the form of compresses. Dr. Cullimore thinks it is likewise active in orchitis and epididymitis.

Communications.

QUININE—ITS USE AND ABUSE.

BY HIRAM CORSON, M.D.,

CONSHOHOCKEN, PA.

Many persons write of quinine and its value in various diseases: to reduce the frequency of the heart's action; to abate the temperature; as an antipyretic in pneumonia; as a promoter of sleep in nervous affections; for the relief of pain in neuralgia; as a tonic in all weak conditions of body; as a remedy for those every-day "bad feelings" which beset many of us; and, above all, as an antiperiodic in all diseases which can be traced to the influence of malaria, and in all others not readily diagnosticated. I need not have spoken of so many diseases, for now we have almost none but malaria and those caused by germs. Even malaria is likely to be displaced as a cause of disease, for all bad-airs are now looked upon as germs which are seeking whom they may devour. We are apt to carry the use of even a good medicine too far; to use it when not needed, oft-times, too, to the injury of the patient; and, even when needed, in extravagant, if not harmful doses. During the last twenty or thirty years such has been the case in relation to the use of quinine. Just before Dr. Brinton ceased to edit the Medical and Surgical Reporter he published an article from a correspondent on the use of quinine, in which the doses used were small, compared with those now in common use; so small that the editor felt that it was needful to call attention to it, by a note appended, in which he stated that *small doses given so far from the expected paroxysm are utterly useless to arrest an intermittent disease.* I do not quote his words. This attracted my attention, and I have since observed that this opinion is in accord with the opinions of those who are in the habit of freely using quinine, and who see a malarious origin in nearly every disease, not due to germs. Large doses given near to the time of the expected paroxysm in intermittent fever—twenty, forty, seventy grains a day; yea, as much at a single dose is vauntingly, triumphantly spoken of as an improvement on old time practice. In view of the opinions and practice of the present time, it has occurred to me that it may be useful to speak of this medicine and its value as a remedy in the diseases in which I have used it for more than sixty years.

Our necessities sometimes teach us valuable lessons. When, in 1826, I began the study of medicine at New Hope, Pa., intermittent fever prevailed extensively along the Delaware river from Bristol to Easton. We hear much now about "malaria." It is spoken of as a *disease*, not as a *cause* of disease. The one disease which every physician in our country acknowledges as the one undoubted malarious affection, is intermittent fever. It was this disease which in the fall of 1826 I had daily opportunities to see in its varied forms, from the simple ague, with its daily shakes, to the tertian with its every other day, and the quartan with its third day paroxysms.

At that time my preceptor told me that he was paying $16 per ounce for sulphate of quinine, and that a few years before that time the cost was $26 per ounce. This price will seem almost incredible to physicians of the present day. Fearing that this statement might be doubted, or attributed to the forgetfulness of old age, I wrote to Powers & Weightman, successors to "Farr and Kirnzic," at that time the manufacturers of the article—and have received the following answer: "In regard to the price in 1826 being about $16, and some time previously $26, we think you are substantially correct." * * * * "We have a friend in Cleveland, Ohio, who said some time ago, that he remembered buying from Farr & Kirnzic, about 1825, at $24 per ounce, and we think he is correct." At twenty-four dollars per ounce, the cost per grain would be five cents. It is easy to believe that a physician who furnished the medicine to his patients had need to be economical in the use of an article so expensive, and would try to discover the least amount on which he could rely to cure an intermittent fever, the principal disease then occupying his attention. Grand opportunities physicians had too, for observing its effects and the amount needed to insure an arrest of the disease. There were hundreds of cases. Every day, or every other, or every third day a chill, of perhaps a whole hour, followed by pain in the head, high fever, sometimes delirium for several hours, succeeded by profuse perspiration, subsidence of the former symptoms, and then for a few hours comparative comfort until the return of the paroxysm and its attendant ills. While some of them would be seriously ill confined to the bed, some others in the same family, would be up during the interval.

As we passed into the fall of 1826 I saw with my preceptor many patients suffering with the various forms of intermittent fever,

which prevailed to a distressing degree on both sides of the river. His inability to attend to all the cases caused him to assign a certain district to the care of another student and myself. This strip of three miles in extent, from "Ingham's Spring" to the river Delaware, was studded with mills and factories, at each of which were a large dam and a long race filled to the brim at night, but drawn down somewhat during the day. Here with these sick men and women, boys and girls, all suffering from some form of fever—which would now be called malaria—we exercised the little skill we had for their relief. My fellow-student had been doing "some practice" for several months before I entered the office, and he, therefore, did the prescribing. Day after day we made our trips up the "race" attending to the sick, and oh! how sick some of them were. There were all the common forms of intermittent and we could generally cure them without difficulty or delay. But there were also some cases which did not get well so readily—were not decided intermittents; these were called remittents, or bilious fevers, and though quinine was used in the treatment occasionally, the great disorder of the stomach, high fever, occasional delirium, pain in the head and almost jaundiced condition of the skin, indicated as we then believed the use of calomel and febrifuges.

In the pure intermittents our usual treatment was ten grains of sulphate of quinine in one or two grain doses every hour, or two hours, dependent on the length of time of the interval between the appearance of perspiration and the time of the expected chill. We deemed it quite important to exhibit the medicine as soon as possible after the abatement of the hot stage and appearance of perspiration; in other words, *as far from the time of the expected chill as possible.* Our practice as you see, was the very reverse of that spoken of and advocated by Dr. Brinton, yet, I do not speak of it as being the proper one, but merely state the fact. If in the interval we could give ten grains every hour, in the fore part of the intermission, we felt almost certain it would prevent another attack the following day, or at farthest, the next day, if the case were a quotidian. Scores and scores of cases were thus arrested, though the patients had such poor doctors. During the sixty years, which have since passed, hundreds and hundreds — may I not say thousands — of cases have I arrested with this small amount of this valuable medicine. After I graduated in 1828, the disease prevailed along the Schuylkill river and throughout my whole region, and my practice was the same as while at New Hope. Called to a patient, I would generally be able from the history given to me, to ascertain whether it was a quotidian, tertian, or quartan. If the first, I gave ten grains as already stated; if a tertian, the ten grains were used in the same way and infusion of gentian ordered for the next day; if a quartan, the same practice was followed, but sometimes ten grains were given twice in the interval. When at New Hope it prevailed so greatly, there were also cases of pernicious intermittent fever, which, if not arrested, generally proved fatal during the third chill, reaction failing to appear. In these cases, as there was a possibility of failure in the ten grain dose, and as the peril was extreme, thirty grains were given to the patient during the interval, by giving three or four grains every hour. In no case which I saw with my preceptor there, did thirty grains fail to save the patient. At the time at which I speak, there came to the place a young graduate of the University of Pennsylvania, born and educated in Philadelphia, where intermittent fever did not prevail. He had probably never seen a case of the pernicious kind, and had had no opportunity to become acquainted with it. He had very influential relatives there and soon had patients. He encountered some cases of pernicious intermittent fever which carried off three prominent men, doubtless from the fact that he treated them as he did his ordinary cases. In 1835 I was called to an apprentice of a joiner, 19 years old, who had had his second chill. I saw him at 2 P.M., three hours after the chill began. He was as prostrate as a man in typhus fever; his parents had been sent for, as he was thought to be "sinking." It was apparent to me that this was a regular quotidian, but a most pernicious one; but, as he had lived through the chill, I felt confident that if I could prevent another he would be saved. The thirty grains were given before day-light next morning. He escaped the chill that day, and the next day he sat in the carriage and rode to his home two miles away, apparently and really well.

I am not now advocating the propriety of giving only ten grains to arrest an intermittent fever, or the safety of trusting a pernicious one to thirty grains, but merely stating facts, and showing the control which these comparatively small doses had over that active malarial disease. The pernicious fever was recognized and noticed by medical writers as early as 1822—possibly earlier. From 1822 till 1832 intermittent and remit-

tent fevers prevailed distressingly in what were then called ague districts; but after the advent of the cholera in 1832, they were greatly diminished in numbers, until 1842, when few cases, comparatively, presented themselves. So numerous were these fevers during the first four years of my practice, that if I were to name the numbers occurring in a single season the statement would scarcely be credited. Many times I have seen a majority of the family suffering from intermittents and remittents at the same time, and in some instances have seen every member of the family ill at the same time, one not being able to help another. And how various were the symptoms of this disease! Sometimes only a violent pain over one eye; in one case severe pain in the "head" of the penis, recurring every day at the same hour. In two cases, uticaria over the whole body, disappearing with the perspiration, to recur again at the usual hour, and all relieved by the quinine, as in an ordinary ague. Wherever the periodicity was well marked quinine in the doses named was an efficient remedy.

In a paper published in the MEDICAL AND SURGICAL REPORTER, July 2, 1887, by Dr. Mary Putnam Jacobi, on "Quinine in Pneumonia," she says: "I do not understand Dr. Corson's general denunciation of quinine as a dangerous agent." It will be seen by this paper that I do not regard it as a dangerous agent, and that in my reference to the proofs, given by herself and six other New York physicians, of the utter uselessness of it in pneumonia in their cases, I (in my review of their experiments) objected to its use because its exhibition was useless, sometimes fatal, by taking up precious time to the exclusion of better means of cure. Now let me kindly say, in her own words: "I do not understand how Dr. Jacobi dare recommend its use in pneumonia after proving its worthlessness in that disease." I regard quinine as next in value to opium, but I am disgusted with the disposition to regard malaria as the cause of every disease (not already assigned to germs), and quinine in large, injurious doses as the remedy. There are very few cases of malarial disease now—not more than one in fifty, so-called. It is so handy, when we can't diagnose a disease, to say it is malaria, that we hear it on all occasions, if not as the disease, at least as that which gives character to and aggravates the real disease, and that the treatment must be of a kind adapted to the entire removal of the malaria from the system. Should a new doctor be called to a case which convalesces slowly, he often finds that "the other doctor has not gotten all the malaria out of your system; no wonder that you could not get well."

About forty years ago "spinal disease" was as prevalent as "malaria" is now; thousands of backs were covered with pustules from the nape of the neck to the sacrum; now it is almost unknown.

In a most valuable paper by Dr. James W. Price, in the MEDICAL AND SURGICAL REPORTER of March 10, 1888, I find the following: "Peacock and Niemeyer have both given up the use of large doses of quinine. Quinine in large doses is unnecessary, useless, and often dangerous." That is strong language, but not too strong; and from the same paper, this: "Dr. Edeson says: 'For some years physicians have been quinine *mad*, affected with what may be termed *cinchoniphobia*. The practice seems to have been, when in doubt give quinine; give quinine any way.' How true this is! But we must not forget that this refers to the abuse of it. That it is a valuable medicine in some other than malarial cases, no one can doubt, even if we had no other proof than that given us by that most observant and experienced practitioner, Dr. T. Curtis Smith, in the MEDICAL AND SURGICAL REPORTER of September 16, 1882. Many of the people who write about malaria and quinine have had almost no experience with either of them. They jump to conclusions from the most trifling causes—fancy they have arrived at a knowledge known to no one else. Let me illustrate. An eminent physician, justly holding high rank as a careful observer and truthful reporter, was called to a young girl, and for two days thought she had worms, and treated her accordingly; but as she did not improve, he questioned her closely and discovered that, prior to her illness, she had been in Maryland. Then he concluded it was malaria, and he gave her 20 grains of quinine, and the next day chloral. She recovered at once. Then he published the case, with this heading: "Chloral as a remedy in Intermittent Fever." He had used before the chloral twice as much quinine as was sufficient to arrest an intermittent fever, but he disregarded that and credited the cure to a medicine which doubtless was entirely useless. This was read by thousands of physicians, and hosts of persons were, no doubt, dosed with chloral as a remedy for intermittent fever, or supposed malarial disease.

The abuse of quinine is beyond credence. A man has rheumatism, it is malaria; tooth-

ache, headache, indigestion, pains in the body, sleeplessness, irritative fever of any kind, carbuncle, catarrh, "kidney trouble," everything but pregnancy (and even every discomfort of that), is malaria. Recently I was told by an invalid, who did not look like one, that "his doctor said he was suffering from malaria which he had contracted three years before; that the doctor who attended him had not gotten it all out of him." I find it is a very prevalent belief with the masses that it is a difficult matter to rid the system of it. In that belief there is this comfort to physicians, namely, that if they be slow in giving relief the patients excuse them, because "we know it is difficult to get the malaria out of the system."

Within a month a friend of mine was in consultation with a physician who was dosing a young man with large doses of quinine, persistently day after day, despite fearful pain in the head; probably brought on by it, under the impression that he had malaria; when it was apparent to the consultant that it was typhoid fever, which copious hemorrhages from the bowels proved it to be.

In the *Medical Standard* of April, 1888, p. 113, is an article by I. R. Spooner, of Dakota, who says, speaking of "Pneumonia in Children," that after some preparatory treatment, "fifteen to twenty grains (quinine) should be given for one or two doses, then three to five grains, every three or four hours thereafter until temperature be reduced, when three or four medium doses should be given during twenty-four hours." He should have added if the child be still alive. All this, months after Dr. Ripley, the Drs. Jacobi, and four others had declared that their trials of it as an antipyretic had proven its utter uselessness in pneumonia. Just such treatment as is recommended by Dr. Spooner has been fashionable with many others, they believing that in large doses it would reduce the heat of the body, an opinion proven to be false by the observations and experience of Dr. Ripley and the five others who discussed the subject in New York and published their opinions in a medical journal.

It is fearful to subject a child to the dangers incident to these large doses of a medicine a few grains of which will make the head of an adult ring, and sometimes produce temporary if not permanent deafness.

—The *Boston Med. and Surg. Jaurnal* states that the Massachusetts General Hosptal has recently been given $50,000 by Miss Helen C. Bradlee, of Boston, as a memorial of her brother, the late L. Putnam Bradlee.

A NEW AND RELIABLE REMEDY FOR COCCYGODYNIA AND PRURITUS ANI.

BY R. STANSBURY SUTTON, M. D.,
PITTSBURGH, PA.

I have, for reasons I do not now care to speak of, regarded this disease as purely neurotic. I have treated it with the Faradic current. One treatment produces immediate relief; a few treatments cure it. Three cells are sufficient; time, five minutes; the frequency of application depends upon the return of pain. The anode is placed over the sacrum and the cathode in the vagina or rectum, or over the sphincter ani muscle. This treatment, so far as I know, is original with myself.

Much has been written of late concerning the treatment of pruritus ani. I desire to add my own suggestion. The best remedy I have ever found is the galvanic current; the quantity required need not exceed five milliampères; the time of application five minutes. The relief is immediate, and the application once or twice daily is quickly curative. The anode is placed over the perineum or base of the scrotum and the cathode against the sphincter ani, or, if required, within its grasp, bringing all the pruritic surfaces between the poles. I claim to be the first, so far as I know, to suggest this remedy for the treatment of this disease. I will ere long have more to say of it.

April 14, 1888.

FUNCTIONS OF THE MUCOUS MEMBRANE OF THE NOSE, THROAT AND EARS.

BY THOMAS F. RUMBOLD, M.D.,
ST. LOUIS, MO.

The mucous membrane is one of the important organs of the body. Upon it devolves functions that are so necessary to some of the phenomena of life, that without it life itself could not be maintained.

This organ is composed of an epithelial layer, a mucous membrane proper and a connective areolar tissue under it. In the epithelial layer are found compound or racemose glands, simple follicles and villi containing groups of blood-vessels in single loops and in net-work. Mucous membrane proper contains blood-vessels—the coats of which are encircled by sympathetic nerves, sensory nerves, muscular fibres and rounded enclosed follicles. The functions of the compound

and simple follicles are to maintain the surface of the mucous membrane in a moistened condition. The epithelial cells that compose the upper surface of the mucous membrane, contribute the same secretion, as also does each epithelial cell that composes the entire layer, as each cell acts as an independent secreting gland. It is seen, therefore, that the moistened condition of the mucous membrane is its normal condition. Please bear in mind that I said the *moistened* condition; I did not say a wet condition, that is, a condition in which the secretions are so profuse as to flow from one portion of the surface to another.

If the quantity of the secretion in the membrane is sufficient to form even a very slight stream, then we would have a flow, or by using another word which means the same thing, we would have a catarrh. It follows, therefore, that every mucous surface from which the secretions flow, even in the least quantity, has a catarrh of its surface. On the other hand, it is only when the mucous membrane is in a moistened state, and not in either a flowing or dry condition, that it is possible for it to perform, completely, the functions that are essential to health.

Some of the functions of the mucous membrane vary according to the location of the organ covered by it. In the nasal and pharyngo-nasal passages, the functions are to warm and moisten the air that passes through them into the lungs. As long as these peculiar functions are not interfered with, pathological changes of a very marked character may occur and the patient be unconscious of them. Even the special sense of smell may be so completely obtunded by inflammatory action, as to cause the patient to be unable to name even the week or month in which he lost the ability to recognize odors of more or less pungency.

In the pharynx the mucous membrane secretes a sufficient amount of mucus, to lubricate the bolus of food as it passes on its way to the œsophagus. If this function is not interfered with, the patient will be unconscious of the presence of a prolifierative pharyngitis, the favorite target of almost every throat specialist, and many general practitioners who take trouble to look at the throat.

In the larynx, trachea and bronchial tubes, the mucous membrane has little other function to perform than to maintain the surface of each organ in a moistened condition, but whenever there is a flow of mucus from either of these passages then they are in a catarrhal condition. In the air vesicles of the lungs, in addition to the maintenance of the surface in a moistened condition, its additonal function is to allow the entrance of oxygen into the blood, and the exit of carbonic acid gas from that fluid. When inflammatory action exists in this locality a flow of an excessive quantity of muco-purulent secretion is observed, the quantity being so great as to soon exhaust the patient.

In the Eustachian tube the ciliated columnar epithelia allow the gradual entrance of air into the middle ear, and thus maintain the normal rarefaction that is essential to normal hearing. In the middle ears and mastoid cells, its function is to absorb the air that enters these cavities through the Eustachian tubes, as without this air absorption we could not have perfect hearing.

In mentioning the uses of the Eustachian canal, all physiologists maintain that it is also a drainage-tube to conduct away the secretion of the cavity of the middle ear. This is an assertion that no one can prove. Most of these authors have forgotten that they had already stated in the first part of their works, that healthy mucous membrane secretes only that amount of mucus that is sufficient to keep the surface in a moistened condition. Besides this, the opening of the middle ear into the Eustachian tube is situated some distance above the floor of the tympanic cavity. In this respect, the opening between the middle ear and the Eustachian tube is similar to the opening of every mucous cavity of the head, such as the antrum of Highmore, the ethmoidal and sphenoidal cavities, the mastoid cells, and the frontal sinuses, in each of which the opening is as far away from the floor of its cavity as it is possible for it to be; and at the same time to be open from the side. If the opening into the left antrum of Highmore was made for the purpose of allowing mucus secretion to enter the nose, then each one of us would have to hold the head so far to the right side that the axis of the left auditory canal would be in a vertical line. To empty the right antrum an opposite position would have to be assumed. To enable one to allow secretion to flow from the sphenoidal sinuses, would require the head to be placed so far forward and downward that the forehead would be on a horizontal line. Even in this position these sinuses would not be entirely emptied. The same can be said of the ethmoidal cavities, and mastoid cells and frontal sinuses. The position which would be required to empty the left antrum of Highmore would not empty any other cavity of the head; while the position that would allow most of the fluid in the ethmoidal sinuses to

escape into the nasal cavities would be such as to retain all of the secretions in most of the other sinuses.

From this it is seen that in not one of these cavities is there a provision for the exit of mucus. Nature never intended that this secretion should be thrown off in the fluid form. It is all to either be evaporated or absorbed.

I think the reason why authors make the Eustachian tube an outlet for the middle ear, is because they find that this function is not inconsistent with the accepted theory of air entrance and exit. As long as they continue to hold to Toynbee's theory, which conceives it to be a canal through which air can pass either way, so long will they continue to consider it a drainage-tube also.

In treating all these passages and cavities, we must constantly keep in mind these varied functions and not interfere with them in the least if we expect to benefit the patient. In fact, it would be as much a fault on the part of the physician to treat one of these cavities without bearing in mind the functions of the membrane lining it, as for the surgeon to treat a fracture of the elbow without bearing in mind the function of this joint. If, in our applications we do anything to hinder this membrane from performing its functions, we shall aggravate instead of ameliorating the patient's complaint. This is the reason I do not use astringents or other irritants, as their effects on the mucous membrane are imcompatable with the performance of its functions.

We have in the inflamed mucous membrane an organ that has lost its functions, or rather is unable to perform these in a proper manner. Our duty is to restore the functions as soon as possible, and every application that will not assist in its restoration will certainly end in increasing the trouble.

We have inflammations of long standing, resulting in great changes in some portions of the membrane, as in the pharynx, which still are the cause of no inconvenience or disability to the patient. But if this same kind of inflammatory process takes place in some other organ, it may occasion a disability or the entire obliteration of some function. For instance, if the proliferation which we have seen in the throat occurs in the nasal passages that are normally small in calibre, it would compel the patient to open his mouth to allow respiration, thus helping to induce the follicular pharyngitis spoken of. If it occurs in the Eustachian tubes it would prevent the entrance of air into the middle ear; and, as this inflammatory process is slow, would be the occasion of that slow loss of hearing which we see in very many ear patients. If it occurs in the middle ear it prevents the ossicula auditûs from responding to the vibrations of the membrana tympani, leaving the patient more or less deaf. From this it is seen that a chronic inflammation may or may not be the cause of inconvenience or disability, and whether it is or is not will depend entirely upon the organ in which it is located.

SPASMODIC STRICTURE OF THE URETHRA FOLLOWING LABOR.

BY LLEWELLYN ELIOT, M. D.,

WASHINGTON, D. C.

The following is the history of a case which I attended recently, and is the first one of its kind with which I have met in fifteen years.

N. P., aged 23 years, born in Kentucky, of nervous temperament, but otherwise healthy, was delivered naturally of a male child, weighing nine pounds, at 12.30 on the morning of December 30. Her pregnancy had been marked by excessive gastritis in the earlier months, and by intercostal neuralgia in the latter, otherwise her health was good. On January 5, at 3 o'clock in the morning, she passed her water, but afterwards failed to do so. Hot applications were made over the region of the bladder, but with no relief; the pain and nervous excitement becoming very great, at seven o'clock in the evening I was called. With much difficulty a catheter was passed into the bladder, and a large amount of strongly smelling urine was drawn. On January 6, at 11 o'clock in the morning, the catheter was again introduced, but with pain and difficulty; at 11.30 at night a cocaine cone was allowed to dissolve in the vagina, the end resting on the meatus urinarius; the catheter was introduced and the urine drawn off; the pain was very severe and the stricture very tight; a soft rubber catheter was substituted for the silver one. On January 7, at 10 A. M., a cocaine solution, then a cocaine cone was applied, a soft rubber catheter introduced, and the urine drawn; pain severe and stricture very tight. At 9 P. M., an oleate of cocaine, 4 per cent., was applied to the urethra; after great persistence the soft rubber catheter was introduced into the bladder; the pain and nervous excitement

were so great that the catheter was clamped at the end and allowed to remain in place all night, directions being given to remove the clamp and allow the urine to pass at 1 A. M. and at 5 A. M. The catheter caused no inconvenience. On January 8, at 10 A. M., the urine was passed through the catheter, and the catheter then taken out. At 8 P. M., the catheter was introduced after much difficulty and severe pain and nervous excitement. On January 9, at 9.45 A. M., the catheter was introduced; the pain and nervous excitement and prostration following its introduction were so great that I determined to leave the catheter in the bladder, so, after clamping it, I gave directions to remove the clamp at 1, at 5, and at 8 P. M. The catheter was removed at 8.15 P. M. On January 10, at 10 A. M., the pain on introducing the catheter was not severe, and the spasm less marked. At 9 P. M. there was very little pain or excitement on introducing the catheter. On January 11, at 11 A. M., the introduction of the catheter caused no pain. On January 12, at 11 A. M., she urinated without assistance.

During the entire time of the spasmodic stricture the patient was taking the bromide of sodium and the bromide of potash, in fifteen grain doses every three hours, and the elixir of the valerianate of ammonia in dessertspoonful doses, but they did not appear to exert any influence on the spasm. In the beginning of the trouble I thought the urethral orifice might be irritated by the vaginal discharges, and to correct the acridity of them I ordered syringing the vagina with a solution of Tyree's compound antiseptic powder. This powder is a combination of carbolic acid, alum, borate of sodium, glycerine, the crystalline principles of thyme, eucalyptus, gaultheria and mint. While this solution had a most pleasing and soothing effect upon the patient it did not in the least affect the stricture. After the recovery of the patient, she informed me that her aunt suffered in the same way at her confinement; so there appears to be in this case an hereditary influence.

Stricture of the urethra occurs frequently after confinements, but if I can credit the unsupported statements of physicians, to whom I have mentioned my experience, they can not have the degree of persistence as in this case, or mention of it would have been made in text-books on obstetrics. While the four per cent. solution of hydrochlorate of cocaine has given me good results generally, I can not see why it should have failed me in this case.

Society Reports.

FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

SEVENTEENTH SESSION AT ORAN, ALGERIA.

(Reported by Arthur C. Hugenschmidt, M. D., Paris.)

First Day, March 29, 1888.

The seventeenth session of the French Association for the Advancement of Science opened on March 29, under the presidency of Colonel Laussedat, Director of the Conservatoire des Arts et Metiers, who delivered his opening address on "The Civilizing Influence of Science as Applied to Arts and Manufactures."

The Section on Medical Science, which is the one that interests us, had not so many members present as at the preceding meeting, which is certainly due to the choice as a place of meeting of the city of Oran, in Algeria, which is separated from France by about four hundred miles of sea. Many members remained at home, rather than risk a sea voyage, so that most of the men known by foreigners, or belonging to and characterizing French medical literature, did not appear. Amongst the members present were Prof. Verneuil, Drs. Blanchard, Delisle, etc. (Paris); Prof. Grasset (Montpellier); Gross (Nancy).

Section on Medical Science.—Honorary Presidents—Dr. Verneuil (Paris); Dr. Mondot (Oran).

President—Dr. Grasset (Montpellier).

Vice-Presidents—Dr. Cros (Oran); Dr. Fonteneau (Oran); Dr. Gross (Nancy).

Secretaries—Drs. Tinier and Bourdorim (Paris); Levy (Oran).

Second Day, March 30.

Prof. Grasset, President.

Treatment of Diphtheria with Perchloride of Iron and Milk.

Dr. Mohammed ben Nekkach (Inkermann), has treated twenty-one diphtheritic patients with perchloride of iron and milk, and has obtained twenty cures, and lost a child of six months. Among the twenty cured are two adults. All these diphtheritic patients have been treated from the beginning of the disease before the period of asphyxia or intoxication. Outside of these twenty-one patients, six others have died; two have refused to follow the treatment; one has been treated by another method in a neighboring town; a fourth one did not follow the treat-

ment accurately; and, finally, the two last are mere cases in which he was called too late by the parents. "To all these patients, most of whom were severely taken," he says, "I gave 25 to 30 gtts. of perchloride of iron in a tumbler of water (this solution being renewed every time it was used up); one quart of milk a day was given. A tablespoonful of each of these preparations was administered every five minutes. In addition to this medication, I have prescribed emetics and painted the throat three times a day with a strong solution of perchloride of iron, which, while taking away the false membrane, at the same time cauterizes the subjacent surface."

He states that when perchloride is administered from the beginning of the disease the false membrane does not extend, but the disease becomes localized.

Dr. Gibert (Paris), remains skeptical as regards the local action of perchloride of iron; he uses it as a tonic, but employs other agents in addition.

Curetting the Uterus in Endometritis.

Mme. Sarraute presents seventeen cases of curetting of the womb for this affection, with successful results. She uses the ordinary method, but with strictly antiseptic measures. She has remarked on several occasions that this intra-uterine treatment, while ameliorating or curing diseases of the uterus, had often a very beneficial influence on the state of the laryngeal apparatus, stopping its congestion and rendering the voice more clear.

Prof. Grasset (Montpellier), does not find it surprising that the laryngeal phenomena should have been modified after a uterine treatment, knowing the relations which exist between the genital and laryngeal apparatus, but he is disposed to think that the modified phenomena were nervous phenomena (paralysis or paresis of the glottis), instead of congestive phenomena.

Valvular Canula in the Treatment of Empyema.

Dr. Rogee (St. Jean d'Angely). After the operation of empyema we often have a small atrophied lung unfit for respiration, with or without a pleuro-cutaneous fistula, which must often be completed by Estlander's costal excision. M. Le Fort, at the last Congress of Surgery, asked whether it was not due to the fact that we leave the opening in constant communication with the exterior air, which freely penetrates into the pleura and presses on the lung.

I have done the operation for empyema twice and have had complete success in both cases. I attribute this success to the apparatus I am using, which prevents the exterior air being felt in the pleural cavity. This apparatus is composed of a canula with two valves, the action of which is a complex one. To these valves is due the fact that the compressed lung is obliged to dilate again. Every time the patient coughs the air contained in the pleural cavity is expelled but cannot return, and so little by little a vacuum is established, which obliges the lung under the intra-pulmonary pressure to expand towards the thoracic wall, while the thoracic wall itself has also a greater tendency to be compressed on the lung through the action of the pressure of the external air, which is no more balanced by the intra-pleural pressure.

On Israelite Circumcision.

Dr. Mondot (Oran), exhibited the *modus operandi* of circumcision as practiced by the Israelites. Having shown the instruments, he described the Jewish method. The first incision always produces a section of the skin, much inferior to that of the mucous membrane; then, instead of incising anew the mucous membrane of the prepuce lower down, the rabbin tears the mucous membrane vertically down to the skin in the median dorsal line. The mucosa of the prepuce is then turned down on the penis as the collar of a shirt. The dressing, which is composed honey and styrax, is then applied and kept there for six or seven days. The hemostatic method used is a primitive one, namely, suction of the cut parts with the lips of the operator. He has never met any cases of syphilis transmitted to the child by the mouth of the rabbin, when he performed suction.

Dr. Seguy (Oran), thinks that hemorrhage does not take place after circumcision as practiced by the Jews, on account of the tearing of the preputial mucous membrane. As to syphilis, it is such a common affection amongst the poorer classes of Jews in Algeria, and so much mixed up with scrofula, that it is a difficult matter to find out what really belongs to the child, or what might have been communicated to him by the rabbin.

Mechanism of Death by Decapitation.

Dr. Paul Loye said: Decapitation, as I have studied it, is very simple and very uniform in its *modus operandi;* it is the complete and rapid section of the neck at a certain level by a cutting instrument. The result ought then to be the same in every case,

placing the individual in an analogous condition, and bringing on death in a similar manner. Such, however, is not the case. If the operation is a simple one the lesions produced are very complex and show themselves as hemorrhages, asphyxia, excitations, paralyses, inhibitory and vasomotor phenomena, etc. The slightest difference in the stroke will produce a notable difference in the individual. I have found, for instance, great difference in a dog or in a man. In the dog we observe very extensive movements, general convulsions, in the head as well as body. In man, however, death is calm, without movements or convulsions; the physiognomy does not change, the body remains motionless. The difference is due to the fact that in dogs death comes with asphyxia. The blood which is left in the head or body can be no more oxygenized, nor get rid of its carbonic acid; moreover, the blood comes out rapidly and leaves the tissues without oxygen; these facts explain the convulsions of asphyxia.

In man these convulsions do not take place, because we have here another factor, the irritation of the nervous system described by Brown-Séquard, which brings on death by arrest, by inhibition. Under the influence of this irritation there is an immediate suspension or abolition of the reflex or auto-motor power of the spinal cord and nerve-centers; and if this auto-motor power is abolished, the asphyxiated blood can have no more action, produce no convulsions. It is also admitted, that in death by inhibition, there is an arrest of the exchanges between the tissues and blood; the blood remains red in the veins. We have then blood which does not become of the asphyxic kind, and on the other hand, nerve-centers which have lost their auto-motor excitability. Under these conditions there can be no convulsions nor general movements. The study of decapitation in dogs and men gives us an example of two types of rapid death. On the one hand asphyxia, accompanied by its convulsions; on the other inhibition—quiet death produced by an immediate arrest of all the functions of the body.

Dr. Vincent (Oran), asked the reason of this difference in the mechanism of death between men and dogs? In the man who is guillotined, he thinks that the weight of the knife striking the neck produces an intense cerebral commotion, which is not experienced by the dog which is killed in a laboratory.

Dr. Loye does not admit this reason, for if there is cerebral commotion, signs of asphyxia would be present in the rest of the body.

Dr. Moreau (Algeria), thought this difference might be explained on the ground that man knows beforehand what will happen, while the dog is absolutely unconscious.

Dr. Milliot (Bugeaud). It is said that in decapitation section always occurs at the third or fourth vertebra; this is a great interval. In such a region it is necessary to be more precise, and to know centimeter by centimeter what a lesion can produce.

Dr. Loye, in answer to Dr. Moreau said, that he had seen two men just before their execution by the guillotine; one was most frightened and terrible to observe, the other was perfectly calm; both presented the same phenomena after death. In answer to Dr. Milliot he said, that certainly a centimeter is important, but that his line of section had passed between the first, second, third to the seventh intervertebral space, and all gave him the same result.

Prof. Grasset thanked the author for his most interesting communication, but said he was an unbeliever in the inhibition theory of death.

Special Deformity of the Hands of Glass-makers.

Dr. Rollet (Lyons), draws attention to a special deformity he has observed in glass-makers, who have been at work for several years. There is a permanent flexion of the second phalanx on the first, specially the ring finger. At the beginning there are no signs of muscular atrophy or subluxation, which later render the disease almost incurable. This hook-hand is peculiar to glassmakers who handle the cane; it is a spasmodic contraction of reflex origin. It is an entirely different lesion from the contraction of the palmar fascia.

Dr. Grasset regards this as another example of professional spasms; it is, he says, a new element for the study of peripheral amyotrophies. It begins by a simple contraction, then ensues a neuritis, and finally muscular atrophy.

On a New Form of Painful Arthropathy.

Dr. Poncet (Lyons), draws attention to a new form of arthropathy, which is characterized by continuous violent articular pains, which have appeared in a long diseased articulation, without any apparent causes or complications. "I have made," he says, "three observations, in all of which the patients had been affected for several years with old arthritis of the knee and hip-joint; twice the articulation had suppurated, but fistulous tracts persisted, and it was only after fifteen or twenty years that pain supervened."

In one case, a young woman, 27 years old, of neurotic temperament, for the past ten years had walked on crutches. After having etherized her, I straightened the limb and applied superficial irritation with the thermo-cautery, and then applied a silicated bandage. The patient as soon as she recovered from the ether complained of terrific pains in her knee and corresponding extremity. I gave her morphia injections without relief, and during the night I had to open the bandage, but the pain remained the same, and kept on for some time. At the end of three weeks she suffered a little less. Since then, five years after my interference, the articulation has always been the seat of pain coming on at irregular times. The extremity is atrophied, and as soon as she touches the floor with her feet she gets those fearful pains.

In two other patients who were suffering a very great deal, and whose limbs became useless, I performed amputation. One of them died after disarticulation at the hip-joint, necessitated by the atrocious pain she complained of in the whole lower extremity and coxo-femoral articulation. In the last case, a woman, 36 years old, who had had for eighteen years a suppurating arthritis with fistulous tracts, was taken with severe pains in 1883. I saw the patient two years afterwards, and tried in every available way to procure her relief. Not succeeding, I amputated the lower third of the thigh. From that moment the pains ceased, and have not re-appeared for more than two years after the operation.

This arthralgia develops itself in old articular lesions not yet cured, and of variable nature. From our observations, the articulation of the knee seems to be predisposed to it; and this form of neuralgic arthralgia seems to be found exclusively in women. The prognosis is a very doubtful one, no medical treatment appearing to be of any use. The surgical intervention must be a radical one.

Antipyrin, Antifebrin and Solanin.

Dr. Sarda (Montpellier), communicated a paper on antipyrin and antifebrin in nervous disorders, and compared them with solanin. He had made one hundred and thirty observations. The first two drugs are excellent nervous sedatives; but they have not an absolutely parallel action; antipyrin is very useful in acute articular rheumatism, in hemicrania, and neuralgias of recent date; in all these cases the superiority of antipyrin is undeniable, as it is also in paroxysmal pains of any nature.

Antifebrin is inferior to antipyrin when it is necessary to combat the above-mentioned pains; it is as good as the former in ataxic pains and chronic rheumatism. In neuralgias of long standing, the superiority of antifebrin is certain.

Against excito-motor phenomena, epileptoid trembling, exaggerated reflexes and tremors, antipyrin gives unsatisfactory results; it has given no great success in reflex spasms of hysterical patients, and has given negative results in painful facial tic. In all these cases, with the exception of paralysis agitans, antifebrin is much better. These two drugs are very rarely followed by accidents, such as vomiting, exanthemata, profuse sweats. Antifebrin is the better supported by the stomach.

Solanin is a nervous sedative which is very useful whenever one wishes to have a depressant action on the spinal cord or medulla; it produces a paresis of the motor nerves, and anæsthesia of the sensitive nerves. It is not efficacious in acute articular rheumatism; it is very useful in muscular rheumatism; acts as well as antifebrin to allay the pain in gastric ulcer, as three of my observations show. It is much superior to both antipyrin and antifebrin in the treatment of old and persistent sciatica, especially in cases of neuritis. It has also an excellent action in ataxic pains. Solanin is a most precious drug as a moderator of motor excitation. Out of two cases of chronic myelitis with fulgurating pains and epileptoid trembling the results have been remarkably rapid and constant. Pain and tremor have been suppressed. In a case of sclerosis in patches with very extensive tremor of the left upper extremity, the results have been still more remarkable; after four days treatment the tremor had almost disappeared, and did disappear completely on the sixth day. In paralysis agitans, painful facial tic, post-hemiplegic hemiathetosis, the results are less certain; but the doses have been too small to allow us to doubt the efficacy in these last cases. The average dose is 5 to 6 grains in the twenty-four hours.

Dr. Grasset said: I insist on the therapeutic value of solanin, which has, however, one objection: it costs two dollars for every 15 grains. It is specially used in medullary symptoms produced by lesions of the lateral column. It is very useful against epileptoid tremors and tremors of sclerosis in patches.

Mycosis Leptothrix of the Pharynx.

Dr. Moure (Bordeaux). Mycosis of the pharynx was described for the first time in 1873, by Fränkel, of Berlin. It is a

very common affection, much more so than is thought, and I myself have given up the record of these cases. The etiology, very obscure, is like all the non-diathetic chronic affections of the pharynx. The functional symptoms may all be missing; they are habitually those of granular pharyngitis. On examination you find, on the tonsils or base of the tongue, little tufts projecting above the mucous membrane; they are sometimes uniform or irregular on their surface, yellowish white in color, and detached with difficulty on account of the penetration of the parasite into the mucous membrane. In an anatomico-pathological point of view, these white tufts are composed of leptothrix buccalis. Inoculation of the same have given negative results. The treatment consists in extracting the tuft and cauterizing the point of implantation with chloride of zinc or lactic acid, or better with the thermo-cautery or galvano-cautery. Hering has found in one case in which he extirpated the tonsil that the parasite had penetrated to the extent of one-third of an inch. This affection has no general symptoms; it is very much like granular pharyngitis. No diathesis seems to favor the appearance of the disease.

Effects of Hydrofluoric Acid in the Treatment of Diseases of the Respiratory Passages.

Drs. Moreau and Cochez (Algeria). Of sixty patients in whom they have employed this treatment, twenty-eight have been ameliorated, four remain in a stationary state, nine have grown worse, four died, eleven disappeared after the first or second consultation, four suffered only with asthma and chronic bronchial catarrh. If this method is not an absolute cure, it is useful and has never appeared useless. We must, however, determine which cases are more apt to derive benefit from this treatment. Hydrofluoric acid appears to act by exciting the appetite, modifying the nature of the bronchial expectoration, and probably in destroying the microbes and their infectious products in that secretion, and possibly in the pulmonary tissue itself. The inhalations are well supported, produce no conjunctival irritation, but a little irritation of the teeth.

Dr. Lausseдat said that at Cannes, Dr. Chuquet, who had been experimenting, had found that all non-advanced tubercular patients were stimulated by inhalations of hydrofluoric acid; he saw their appetite return, but he had never seen the cavities in the lungs beneficially influenced. He has also observed that those patients who had, and those who had no cavities, always had Koch's bacillus in the sputa in the same proportions.

Dr. Loye thinks the anti-microbe action of this acid is not demonstrated. He also does not believe in those very difficult and complicated ways of establishing inhalation-rooms for the treatment with this gas.

Third Day, March 31.

President, Dr. Grasset.

Dr. Pauly (Oran), read a paper on

The Algerian Climate; Resistance of the Algerian Cattle to Certain Contagious Diseases.

Dr. Brémond (Oran), read a paper, giving an account of the resistance of the Algerian cattle to malignant pustule and sheep-pox. He then demonstrated that immunity is acquired and lost according to the conditions of living.

Prof. Verneuil (Paris). The question of immunity is a very contested one; one ought to enquire whether immunity is not due to the fact that the animal had already contracted the disease while very young, or perhaps, that it is issued of parents already vaccinated or which had suffered from the disease. It would be an interesting fact to follow a bull which may have been spontaneously cured and search whether his descendants are also preserved from anthrax. Another question interests me, the one of latent microbism. When a bull has been cured I would like to have him under observation for months, and have his blood accasionally examined to see how long convalescence persists; for we know that if a vaccinated bull several weeks after this operation wounds himself, at the wound *minoris resistentiæ*, appears sometimes an anthrax tumor. In human medicine we have similar facts: a man cured of typhoid fever is apparently well; for one reason or another he gets an abscess; if you open it you will find in it the microbe of typhoid fever.

Abnormal Forms of Cancerous Cells.

Dr. Nepveu (Paris). I desire to draw your attention to certain rare cellular forms, which I have met in certain epitheliomas of the tongue and penis. In all these cases the epithelioma had invaded the deep tissues and the glands themselves.

The first type consists of small, nearly round cells, epitheloid, with one or two very fine prolongations, equalling one, two, four, five times and more the diameter of the length of the cell; which prolongations terminate sometimes by a free extremity, at other

times by a finely granular swelling, fusiform in appearance, sometimes terminating on one of the irregular borders of an epithelial cell of large volume.

A second type, which the author has termed conjugated, is a little different. The cell instead of being round is oval, with a rounded head; one single prolongation longer than the preceding one presents a fusiform swelling in the middle of its length and at the extremity of a break at the point of insertion on a neighboring cell. The clearest forms are those in which two cells, clearly epithelial, are united by a more or less long prolongation. Some of these conjugated cells are of different types. Some are irregular and show at their angles very fine ramifications; the others are very large flat cells, although also fusiform. One can see the polygonal cells united by a prolongation to one of these flat cells.

It is not rare to see epithelial cells presenting three or four prolongations, which it has been impossible to follow in all their extent; but everything makes me think that, like the others, they are united to other cells. In a word, in deep epitheliomas, one can find epithelial cells with ramified and multiple prolongations like the multipolar nerve cells. These prolongations unite epithelial cells to each other. These cells called conjugated, are formed sometimes by young cells united to an old, well-developed one; sometimes by well-developed cells united to each other. In certain cases it appears that these epithelial cells are united to fusiform but flat cells, analogous to certain cells of connective tissue.

Tuberculosis in Those Living at Mineral Springs.

Dr. Laussedat (Royat) finds that, while tuberculosis was very rare at Cannes twenty-five years ago, it is at present very common, especially in children and young people, without one being able to trace it to heredity. This is especially due to the dissemination of the tubercle bacillus brought there by tubercular patients. Hence it becomes necessary to have the schools kept absolutely clean, and the furniture which has been used by phthisical patients thoroughly disinfected, or even destroyed.

Intra-venous Injections of Salt-water.

Drs. P. Loye and Dastre. If one injects into the veins of a rabbit salt-water containing 7 gms. of chloride of sodium for each 1000 gms. of water, one can, on following certain indications, throw into the circulation an indefinite quantity of liquid, equal to, and even greater than the weight of the animal. The most important fact is that the injection should be made in a definite manner, not more than 2 grammes being injected per minute for each kilogramme of the animal's weight, and that the liquid should have a temperature of 102° to 104°. Under such conditions we find that there exists in the organism a real regulator apparatus for the quantity of water in the blood. Every time that in a rabbit weighing three kilogrammes, you inject into the blood 300 gms. of salt-water, the animal will urinate; and then, if the injection is continued, the animal continues to urinate, keeping in his circulatory apparatus the same quantity of 300 gms. of salt-water. From this fact there is a regular parallel between the number corresponding to the injection of salt-water and the number indicating the emission of urine. Gradually the urine loses its turbid and yellow appearance and becomes absolutely clear. You can in this manner, allow the passage into the circulation of an indefinite quantity of water. During all these operations, the blood pressure is not changed.

If you put more than seven grammes (2 drachms) of chloride of sodium to a litre (two pints) of water, you get a temporary glycosuria. The injected liquid remains in the blood, the aqueous portion of the same being then increased. He has also never noticed any bad effect on the kidneys.

Dr. Grasset. These injections might help us to increase diuresis, and a washing out of the blood. This is what we do when we give large enemas of water to patients with jaundice. The water is absorbed by the intestines, thence taken into the vascular system, and is finally rejected by the kidney loaded with bile.

Experimental Researches on Submersion.

Drs. P. Loye and Brouardel. If a dog be suddenly plunged under water he will die in three and a half to four minutes. He first takes a very deep inspiration, called "surprise inspiration," which fills a great portion of the respiratory passage with water. Sometimes a second inspiration will take place, then the period of resistance appears, the animal has stopped inspiring. This lasts a few moments, and is accompanied by general movements. Then he begins to inspire again and the movements stop. Finally, respiration stops, sensibility is lost, and the animal is dead. If we observe the circulation, we will find the heart's movements diminish one-third or one-half, but the strength of each beat is increased as well as the blood-pressure, and they remain so until death; the beats are sustained, but the blood-pressure decreases gradually until the last inspiration is taken,

when it is down to zero. The heart, however, will still continue to beat for about fifteen minutes after the last inspiration, the blood-pressure remaining at zero. The period of resistance which follows the deep inspiration is not due to the will, for we find it in tracheotomised dogs, but is due to an action on the superior laryngeal nerve, which brings reflexly into action the respiratory nerves. The water introduced into the lung will help to dilute the blood, before and even after death. The legal physician who is called to determine whether a drowned person was alive when thrown into the river, or if he was already dead, tries to get his information from the state of the blood as to its being coagulated or not. He concludes that death occurred by submersion if the blood is found liquid. But we have just seen that water will pass into the circulation after the patient is really dead, and that even in drowned persons the blood will be found coagulated if examined soon after death; the blood will also be found liquid in the large vessels and right heart.

On the Use of Biniodide of Mercury in Surgery.

Dr. Rogee (St. Jean d'Angely), claims for it that it does not irritate the wounds. It is a much stronger antiseptic than carbolic acid, and an alcoholic solution of 1 to 300 can be mixed in all proportions with warm water. It is much less expensive than Lister's dressing. He has used it in 108 operations, 32 being major operations, with one death. On an average, cicatrization was obtained in seventeen days after an amputation of the thigh in a malarial patient, and in ten days after herniotomies.

Spinal Meninges in the Sacral Canal, and the Filum Terminale.

Dr. Trolard (Algeria). The classical authors give as terminations of the dura mater and arachnoid, *cul-de-sacs* at the end of the sacral canal. Even in children this *cul-de-sac* stops on a level with the second sacral vertebra, the canal from this point being filled with nerve branches and a great deal of adipose tissue. A fact worthy of notice is that the ganglions of these nerves are situated in the canal itself. As to the filum terminale, it is probably the common trunk of the two last pairs of spinal nerves; if one examines it carefully he will find that it is divisible into these nervous branches, but its termination is very variable.

Lakes of Blood of the Dura Mater.

Dr. Trolard describes them as follows: The veins which open into the superior longitudinal sinus are described as opening into that canal in a direction contrary to the blood current. This is not quite true. The little veins, especially the anterior ones, open directly, or from before backwards, into the sinus. As to the two or three large veins, they communicate with the sinus from behind forward. But one must not overlook the fact that these anastomotic veins place in communication the superior longitudinal sinus with the superior petrosal and lateral sinuses. These anastomotic veins which are accessory to the great sinus must have the same direction that this last one had.

Reports of Clinics.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

MEDICAL CLINIC—PROF. PEPPER.

Lithæmia With Grave Nervous Symptoms.

The patient is 29 years of age, a physician by profession, having graduated from the Medical Department of the University of Pennsylvania in 1885. His family history is remarkable for the singular unanimity with which all its members are disposed to disease of the same organ—the kidney. His father and mother were both of a markedly nervous diathesis; throughout their lives they both exhibited a strong tendency to renal troubles, and, finally, both of them died of Bright's disease. An uncle was afflicted with *petit mal*, and three brothers and a sister of the patient have all, without exception, gout and gravel. While yet a child, he had an eclamptic seizure produced by the passage of some renal calculi. Speaking generally, however, such attacks in childhood have but trifling significance, slight causes being sufficient to produce them.

The patient has always been rather sickly, and yet, in spite of his want of bodily vigor, he has been a hard-working and faithful student. He pushed his way through the University of Virginia, and subsequently came here and graduated in medicine. Eight or ten years ago, while he was still pursuing his studies in the South, he first became aware of the fact that occasionally on awaking in the morning his tongue was more or less lacerated around the tip and edges, as though it had been bitten. About this period, also, he began to have irregular attacks of nervous prostration and violent headaches, which were relieved only by free

purgation. During his term of study in this city, he was an almost constant sufferer from nervousness and lithæmia, being treated at odd times for gravel, sciatica, insomnia, etc. He was told by his room-mate while here of the occurrence of nocturnal epileptic seizures, and in these was found an explanation of his wounded tongue. During the last few years the symptoms of renal trouble have become much more prominent. He is not conscious of having passed any calculi for a very long time, but he complains of severe and continuous pain originating over the region of the right kidney, extending down the ureter of that side, and thence along the course of the genito-crural nerve in the groin and to the bottom of the testicles and scrotum. As often as once or twice a month a sudden exacerbation of this pain precipitates a series of convulsive paroxysms which are most violent. The muscular contractions attending them are tonic in character and limited usually to the right side, the leg and arm being drawn up and held rigid for five minutes or more. Then there is a period of relaxation, lasting generally for about twenty minutes, and this is followed by a recurrence of the spasm. A series of these phenomena may endure for a few hours only, or continue throughout two days. During such attacks there is no loss of consciousness, but the patient says he feels as though he would become insane at times from the agonizing pain that accompanies them. Within a comparatively recent period, also, he has had four epileptiform seizures, *petit mal*, occurring in the daytime, and characterized by a very transient suspension of consciousness, a momentary fixation of his eyes, and slight twitching of some of his muscles.

Examination of the urine shows it to be typically gouty in character. It is of high specific gravity, acid in reaction, high colored, and loaded with urates.

We have here, then, a long and connected history of renal derangement occurring in a man the members of whose family are all strongly disposed to kidney complaints as well as to various neuroses. His disease is inherited; it first gives evidence of its existence in early childhood, and it continues and gains strength with advancing age. When about 19, the patient begins to have attacks of nocturnal epilepsy, occasional fits of nervous prostration, severe headaches, etc. In spite of these difficulties, however, he continues his studies, graduates from college, and enters upon the practice of his profession. At this time we find his symptoms becoming of a mixed character. In addition to the nocturnal epileptic seizures, he has several attacks of *petit mal* in his waking hours, and, besides these, on two or three occasions he tells us, prolonged periods of unconsciousness, without, however, any convulsive phenomena. These latter are known by the name of "status epilepticus." Moreover, the symptoms of urinary disturbance take on increased energy; he suffers from constant pain over the right kidney and in the right groin. Once a month, or perhaps, oftener, this pain undergoes a sudden and intense aggravation, and, at such times he has simultaneous attacks of right-sided convulsive seizures, and, sometimes, when the pain is unusually severe, the arm of the left side participates in these movements. These seizures are in the highest degree interesting and curious. They are certainly not epileptic for throughout their entire duration, be it brief or prolonged, perfect consciousness is maintained. To such attacks as these is given the name of "hemi-spasm." Their occurrence is ascribed to the irradiation of powerful motor impulses proceeding from nervous centres, which are kept in an almost constant state of irritation and excitement by the morbid condition of the blood which nourishes them. From time to time there occur periods when defective coordination between the great abdominal viscera, the kidneys, liver, and stomach, is followed by serious vitiation of the blood. The processes of secretion and excretion are interfered with or temporarily suspended, and the blood becomes loaded with effete products which, when in sufficient quantity, quickly manifest their power of exerting an actively poisonous influence. The nervous centres, bathed in this toxic fluid, become intensely irritated, they become even more morbidly sensitive than usual, until, finally, when nervous tension has reached a point beyond which it cannot go, there is a sudden explosion of force manifesting itself in these violent muscular contractions. At such moments comparatively slight causes are sufficient to overthrow all inhibitory influence, and give free rein to these irregular exhibitions of energy. In this particular case, these phenomena are brought out with exceptional clearness.

Now, after this hurried rehearsal of the more important points of the case, we have to ask ourselves first, What is the source of the intense pain which precedes and gives rise to these attacks of hemi-spasm? During the periods when it is present, it is too persistent in character to be regarded as neuralgic. Upon considering the region from

which it takes its origin, and the course over which it travels, our attention is strongly attracted to the right kidney. As I review in my mind the history of this man's sufferings, his undoubtedly gouty diathesis, the many significant symptoms he presents of renal disorder, and the frequent and severe reflex disturbances which have that region for their starting-point, I am led by the mass of accumulated evidence, to believe in the existence of calculous deposits in the substance of this right kidney. The calculi are certainly not contained in the pelvis of the kidney, because urinary examination negatives the existence of pyelitis. I am the more strongly inclined to put faith in this diagnosis, because I remember with painful distinctness, an obscure case, closely resembling this in many of its leading features, in which the autopsy disclosed a number of calculi disseminated throughout the substance of one kidney. In case, therefore, other methods of treatment should fail to give this patient relief, I shall strongly urge upon him the propriety of having his suspected kidney removed.

Preparatory to any resort to surgical measures, however, I shall put him upon the following plan of treatment: In the first place, to obtain a strong and continuous counter-irritant effect, we will establish an issue over the diseased organ. Second, a powerful galvanic current will be passed at intervals through the centre of the area of disturbance. Third, a plan of diet will be adopted which will largely diminish the formation of uric acid, and of which milk and cereals will be the principal components. Fourth, and last, a course of bromides will be prescribed by which 7½ grains each of the potash and soda salt will be administered three times daily.

In addition to these more important points of treatment, a system of graduated and regular exercise will be carried out, which will prove of much assistance, not only by improving the patient's general health and vigor, but by diverting his mind and preventing it from dwelling upon his malady.

—A physician in the *American Magazine*, illustrating the evil custom of talking to an invalid about his pains, says that once he requested a mother to mark a stroke upon a paper each time that she asked a sick daughter how she was. The next day, to her astonishment, she made one hundred and nine strokes. A three months' visit away from home was prescribed.

Periscope.

The Antiseptic and Antipyretic Treatment of Phthisis.

Dr. W. H. Spencer, Lecturer on Medicine, at the Bristol Medical School, England, in the report of some cases illustrating the antiseptic and antipyretic treatment of phthisis (*British Med. Journal*, January 28, 1888), speaks as follows with reference to the use of iodoform and eucalyptol:

"1. I see no reason to doubt that, when iodoform is given in doses which the stomach will tolerate well, and given frequently and continuously for long periods, it is absorbed into the circulation; and in the lungs, in whatever form it be, manifests its antiseptic (shall I also say, antibacillary?) properties. The good effects of iodoform so administered, in phthisical conditions, is too unequivocal to be gainsaid.

"2. I see no reason to doubt that, when the vapor of the oil of eucalyptus (or other antiseptic vapor that can be tolerated equally well) is inhaled continuously and for long periods, it reaches the residual air in the lungs; and so externally, as it were, bathes the affected tissues, or suppurating cavities, which may be open to the ingress of the air.

"3. That so, I apprehend, we may have antiseptic remedies, not antagonistic, brought up on two sides to the sites of inflammatory lung lesions, or the sites of bacillary activity; and these antiseptics, mutually co-operative, do affect for good both the inflammatory process and the bacillary activity, and bring about repair by the mode of organization after suppuration or fibroid substitution.

"4. And further, let me say, that I think it is both correct and desirable to treat the pyrexia of acute phthisical processes, whether the temperature be high or moderate, by and for itself. I think no other special antipyretic than quinine should be used in phthisis; and quinine serves other purposes as well when used as an antipyretic in moderate doses." He sums up the whole of his paper in some remarks on what he conceives to be the practical outcome: "In our treatment and general management of these cases, it is our aim to promote or bring about healing of the damaged lung tissue, and this by means of fibroid substitution. In order to attain this end, we must secure the same conditions and adopt similar measures, if we can by any means compass it, to those we find successful in dealing with suppurations, ulcerations, and the like lesions, in parts exposed to view. To secure these conditions, we should adopt measures for supplying adequate nutrition—

that is, adequate anabolism of tissue and the storing of energy—in the body generally, and in the damaged part in particular. We should deal with pyrexia on its own account, as a general and constitutional state, apart from the local suppuration or ulceration (as by quinine). We should bring the lesion under the influence of antiseptic remedies, both by internal medication (as by iodoform), and by external applications (as by inhalations of eucalyptol); and the application and influence of the antiseptic should be complete, continuous and prolonged."

Simultaneous Presence of Cancer and Tuberculosis.

In *Virchow's Archiv*, Bd. cxi., Heft 2, Feb., 1888, Dr. Otto Lubarsch, of Breslau, in a communication upon primary cancer of the ileum with some remarks upon the simultaneous occurrence of cancer and tuberculosis, concludes that:

1. The relatively infrequent occurrence of cancer and tuberculosis in the same person, is not adequately explained by reference to the different periods of life during which these two diseases are most frequent.

2. It is not true that cancer of a particular organ, such as the œsophagus (Lebert) predisposes to tuberculosis.

3. Acute infectious diseases, as well as phthisis, are proportionately much rarer in patients with carcinoma than in non-carcinomatous patients of the same age.

4. Tuberculous affections, as well as chronic local wounds, may favor the development of a cancer.

Spontaneous Expulsion of a Fœtus after the Death of the Mother.

In the *Deutsche med. Wochenschrift*, December 15, 1887, Dr. Theopold says that during the inspection of the dead body of a woman, the fœtal head surrounded by the membranes was expelled from the vulva. This statement was sent to him for his *superarbitrium*. The woman, who was far gone in pregnancy, had died of hemorrhage. The neighbors, who had been summoned by the husband, found her dead. The corpse had lain fourteen days in the grave, and was exhumed on a hot day in August, and had been exposed some time to the open air. The belly of the woman was greatly puffed up with gas. Evidently the pressure of the gas, the tension of which had been raised by the heat, had expressed the contents of the uterus.

The suspicion that the husband had ill-treated his wife and so caused her death led to an official autopsy, and the disagreement of those who conducted this autopsy to the giving of a *superarbitrium*. It was assumed in the latter that birth had begun and that premature separation of the placenta had been the cause of the fatal hemorrhage. As the autopsy did not reveal definite traces of the woman having suffered ill-treatment, and as there were no witnesses to any, proof of a crime could not be adduced.

Complex or Vertical Hermaphroditism.

At the meeting of the Pathological Society of London, Feb. 21, 1888, Mr. Stonham exhibited a case of complex or vertical hermaphroditism. The child had been operated upon for hernia, and the contents of the sac were returned to the abdomen; the wound suppurated, and the patient died. The external organs were of the male type, with undescended testes; the bladder was normal in size and shape, and its neck was surrounded by a prostate. Behind was a vagina and uterus, the latter being devoid of a projecting external os, but having a distinct cervix. On each side of the uterus were testes, and below them Fallopian tubes and epididymis. The family history was interesting, one sister having a bifid nipple, and two brothers each a well-formed penis and scrotum, but no testes. Mr. Sutton thought the case proved that the prostate was homologous with the cervix uteri. Mr. Jonathan Hutchinson Jr., opposed this view.—*Lancet*, Feb. 25, 1888.

Tumor of the Stomach produced by Hair; Gastrotomy; Recovery.

John Berg, who reports this case, states that the patient was a married woman, twenty-six years old, who had suffered from the third year of her age with dyspeptic and anæmic symptoms, but especially with vomiting of mucus. A tumor in the epigastrium had become evident since her tenth year, and had developed rapidly during the past six months. She entered the hospital in Stockholm in May, 1887. At that time there could be felt in the epigastrium and in the left hypochondrium, between the prolongation of the right parasternal line and the left mammary line, a tumor the size of a hand, movable, and having a concave superior and a convex inferior border. The tumor could not be displaced toward the region of the kidneys. The spleen was in its normal position. Laparotomy was performed, and in the stomach was found a tumor, which consisted of a bunch of hair.

The patient denied having ever eaten hair, but her mother said that when three years old she was in the habit of chewing and swallowing hair.—*Nordiskt med. Arkiv*, Bd. xix., No. 26, 1888.

Washing out the Pelvis of the Kidney and the Ureters through the Bladder.

In a communication in the *Lancet*, March 10, 1888, Mr. Reginald Harrison refers to the possibility of distending the ureters with fluid, and thus reaching the pelvis of the kidney. In the normal condition of the parts such a process could be brought about only by very gradual means, as the mode of entrance of the ureters into the bladder is such as to render sudden regurgitation of fluids from the latter toward the kidneys well nigh impossible. But in long standing stricture and prostratic obstruction, this valve-like arrangement becomes impaired until the ureters and pelvis of the kidney become little else than subsidiary bladders. The same thing occurs as the result of the passage along the ureters of calculi and suppurative *débris*, as is frequently seen in tubercular disease of the kidneys. It occurred to Mr. Harrison that when such conditions exist fluid might be made to pass from the bladder along the ureters to the pelvis of the kidney. The author then refers to cases in which these theoretical considerations were put to a practical test. In all these cases renal calculi, or fragments of them, were successfully dislodged from the ureters by distending the bladder with fluid.

Treatment of Ranula.

Verchère recommends in the *Archives de Laryngologie* the treatment of ranula by puncture and injection of a ten per cent. cocaine and a one-tenth per cent. chloride of zinc solution. The tumor is punctured with a Pravaz's syringe and emptied by aspiration. The canula is left in the sac, into which is then injected half a syringeful of a ten per cent. solution of cocaine, followed by ten or twelve drops of a one-tenth per cent. solution of chloride of zinc in distilled water. The inflammation which follows is usually not very violent, and recovery is rapid. In the place occupied by the ranula there remains a small nodule, which occasions no disturbance.—*Wiener med. Presse*, March 25, 1888.

Quinine Amaurosis.

Dr. Edgar Browne (*Liverpool Med. Chir. Journ.*) points out the difference between quinine and tobacco amaurosis. Alluding to a case of quinine amaurosis, he says: "The ocular symptoms in this (and other recorded cases) are very remarkable. After an interval of total darkness, recovery commenced by a rapid restoration of central vision, the peripheral retina remaining quite useless both for form and color. The movements of a flame can be perceived all over the field, but not those of the hand or any non-luminous object. Within the central area vision is practically perfect. The patient sees as through a small hole clearly, but nothing above, below, or to either side of him, and as a consequence, though he can read the smallest print, he runs against lamp-posts and upsets people in the street in the most amazing fashion. The condition is exactly opposite to that observed in tobacco (or central) amblyopia, where the patient cannot read print but is able to move about crowded streets, to ascend the rigging of a ship, or avoid vehicles with little or no diminution of his accustomed facility."—*Medical Chronicle*, March, 1888.

Weil's Disease.

In the *Deutsches Archiv für klinische Medicin*, Bd. xlii, Heft. 4, Dr. A. Fiedler gives the following summary of this disease, which was first described by Weil in 1886: It is an acute infectious or toxic disease which has nothing in common with abdominal typhus nor with any other known disease, but is a disease *sui generis*. It begins quite without premonitory disorder, and often suddenly, with a chill. Symptoms always present are fever, headache, gastric disorder, jaundice and muscular pains, especially in the peronei. The fever has a typical course and continues from eight to ten days. Occasionally after the fall in temperature, which takes place gradually, a relapse of the fever occurs. The pulse at the beginning of the attack is frequent, but subsequently becomes sub-normal. The spleen and liver are frequently, but not always swollen, and the liver is often tender upon pressure. Nephritis is frequently present, and at times herpes and erythema. The prognosis is generally favorable. It attacks especially men in the prime of life, and appears preferably in summer. The bearer of the disease is still entirely unknown; but the circumstance that among twelve male patients nine were butchers, makes it probable that men of this occupation are affected in a higher degree, or more easily, by the noxiousness which causes the disease, than are other persons.

—Dr. Schiefferdecker of Göttingen has been appointed prosector of anatomy in the University of Bonn.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 7,500 copies.

THE SYMPTOMS AND TREATMENT OF HERNIA OF A MUSCLE.

The occurrence of a protrusion of a part of a muscle through an unnatural opening in its sheath has been recognized for many years, and it is known in works on surgery as hernia of a muscle. It has sometimes been confounded with rupture of a muscle; but when correctly understood, the term applies solely to what we have described above. The subject has been well studied by Farabœuf, about seven years ago, and most recently by DR. AIMÉ GUINARD, of Paris, who reports the results of his study in an interesting paper in the *Gazette Hebdomadaire*, April 6, 1888. In this paper Guinard points out the errors contained in most descriptions of this injury, and gives an explanation of its phenomena which is entirely consistent with the mechanical conditions which must be present. The most conspicuous error in the previous descriptions consists in the assertion that the tumor caused by hernia of part of a muscle increases in size when the muscle contracts. In order to get at the truth in this matter Guinard made a number of experiments on living animals, and found that after removing part of the sheath of a muscle, there was no hernia when the muscle was inactive. When the usual action of the muscle was imitated by force, and it remained inactive, there was a protrusion. This protrusion disappeared when the muscle was stretched by an action opposed to its own. It disappeared also when the muscle contracted while its action was opposed. It diminished in size and became harder when the muscle contracted actively without opposition.

These facts indicate, as Guinard says, the phenomena which ought to be looked for when there is reason to suppose that hernia of a muscle has taken place. A thorough understanding of them compels the conviction that the cases so far reported, in which it is stated that the tumor became larger and harder when the muscle contracted, were really cases of rupture, and not of hernia of a muscle. As stated above, a hernia under these circumstances must become smaller, and not larger.

There is only one other condition in which the phenomena of hernia of a muscle may be present, and that is when the aponeurosis of a muscle is thinned and weakened at some spot, so that it no longer offers the normal resistance to the muscle itself. A case in which this actually occurred is reported by Guinard.

The rarity of real hernia of a muscle gives peculiar interest to two cases reported by GIESS in the *Berliner klinische Wochenschrift*, No. 11, 1886. In these cases the nature of the lesion was established by cutting down upon it. They also afford a means of determining what is the best treatment for this lesion. In one of Giess's cases, strapping and bandaging did no good, and so he exposed the tumor by an incision, snipped off the protruding portion of the muscle with scissors, and afterwards cauterized a new protrusion with nitrate of silver. The result was unsatisfactory. In the second case Giess cured his patient by cutting down upon the protrusion, removing

it with scissors, freshening the edges of the rupture in the fascia, and suturing them with catgut. After this the external wound was sutured, and the limb—a leg—was confined in a plaster-of-Paris dressing.

We call the attention of our readers to this curious and rare lesion, and to the best way in which to treat it, in the hope that American surgeons may contribute something to confirm or correct the views which we cite.

ABUSE OF PRIVILEGE BY PHYSICIANS.

We have so often had occasion to praise the fidelity with which physicians, as a rule, perform the duties of their office, that it cannot be regarded as an evidence of want of appreciation that we call attention to a matter in which physicians sometimes abuse their privileges and misuse their powers. This matter has recently called forth a cutting paragraph in *Life*, April 12, 1888, in which it is stated that there is a medical precedent for the acquittal of Mr. Jacob Sharp, in the case of a Mr. Thomas Gould, who, when sentenced to imprisonment, acquired quick consumption, and, according to the physicians—"one of whom, by the way, is now attending upon Mr. Sharp"—could be saved only by release from confinement.

The point of this paragraph is obvious. Its application is somewhat weakened by the fact that Mr. Gould was set free and is still living, and that Mr. Sharp was kept in prison and is now dead. But this does not impair the force of the principle involved, or dispose of the insinuation that physicians sometimes permit themselves to be used by criminals as a means of escape from merited punishment. There is good reason to believe that this sometimes actually occurs, and when it does occur, it is a disgrace to the profession. The effect of its rare and occasional occurrence is to lower the medical profession in the eyes of courts and of the community; and to weaken the influence which it ought to have with both. The temptation to yield to the entreaties of those who find themselves in the grasp of the law, from motives of pity or to secure a reward of money or notoriety, may have little influence with those who are called to pronounce upon the physical condition of a prisoner; but the world is apt to judge by appearances, and to conclude that what exercises so much influence upon other men may affect the judgment of physicians also.

For this reason, it may not be amiss to call the attention of our medical brethren to the importance of exercising the utmost caution in interposing the shield of their professional authority between the law and those with whom it is dealing. In this case an error of judgment, or weakness of will, may lead to consequences as serious as would follow absolute rascality; and even the too zealous following of a scientific conviction may bring discredit upon the whole medical profession. In the middle ages the right of sanctuary was so abused that it had to be abolished; and in our age abuse of the protecting power of medical opinion might lead to the utter loss of this power. Such a result would be as unfortunate for the community as it would be for the physician; and we appeal to the members of our profession, for the sake of the really unfortunate, and of those who wish to be just but not vindictive, as well as for their own sake, to see to it that they never abuse their privilege or bring discredit upon one of their most important functions.

THE NEW YORK HERALD AND HYDROPHOBIA.

The occurrence of a few cases of so-called hydrophobia in various parts of the United States of late has furnished the New York *Herald* an opportunity to fan the dying embers of this disorder, and to excite anew in the minds of the community those fears which the members of the medical profession in this country have been working so faithfully to allay. We have investigated a number of the cases reported as hydrophobia by the New York *Herald*, and have found them to be spurious. It is no great damage to the reputation of this newspaper to say that its utterances in regard to hydrophobia are characterized about equally by ignorance and recklessness, and there is little reason to hope

that it will mend its ways for so small a consideration as this. For years it has seemed to be under the impression that it was a noble mission to increase the popular fear of hydrophobia, and has seemed to enjoy the publication of sensational and terrifying details of cases of so-called hydrophobia. This might not be a very dangerous pastime, if it were not for the fact that it is probable that the New York *Herald* is read by a large number of people who are more gifted with curiosity than with wisdom; and we should not call attention to the matter at all, were it not for the fact that we wish to enlist an active opposition on the part of intelligent medical men to an influence which is too serious to be simply ignored. Whenever a daily newspaper begins to publish the details of cases of so-called hydrophobia, there is apt to be a revival of the popular fear of this disorder, and a multiplication of the number of persons suffering with its symptoms. Fortunately for us, the influences which keep up the excitement about hydrophobia in France, and which keep up the number of cases of so-called hydrophobia there, are not active here; and even the New York *Herald* cannot turn back the tide of common sense which every year reduces the mortality from this disorder in the United States. But we think it worth while to characterize its conduct as we believe it deserves to be characterized, and beg our readers to remember the reputation which this particular newspaper has acquired by years of consistent editorial management, when they read its statements of fact or its utterances of opinion on medical subjects.

VACCINATING ESTABLISHMENTS.

The proposition to create an establishment for vaccination in Paris seems to be nearing its accomplishment. The *Gazette Médicale*, March 31, 1888, states that a Commission has been appointed to prepare a plan for such an institution, and that the results of its deliberations will soon be made public. The fact suggests the thought that it might be of advantage to have establishments for the purpose of vaccination in American cities also. At present vaccination is effected in this country in a somewhat desultory fashion, and there is no universally recognized source from which good vaccine virus can be obtained. In the intervals between epidemics of small-pox it is always hard, and sometimes almost impossible, for individual physicians to obtain virus of known good quality; and when an outbreak of small-pox creates suddenly an increased demand for vaccination the resources of physicians are taxed to the utmost. This, we think, would be less likely to be the case if some recognized medical body would found an establishment in which vaccination should be practiced for a moderate fee by persons selected for that special purpose. In such an institution—if it were well supported by the members of the profession—the demand for vaccination would be constant enough to secure a steady supply of good and reliable virus, and medical men would feel safe in recommending their patients to go there for the vaccination of themselves or their children, instead of taking the risks inseparable from the use of such virus as they can secure. In such an institution bovine and human virus could be systematically propagated and a fair test be made of their respective merits. The service of the establishment could be conducted on the same general principles as now govern hospital clinics, and an arrangement might be made for a scale of prices differing at different hours, so that a certain respect should be paid to social distinctions which it might be wise to recognize.

We believe that some such plan as we have now outlined would not be impracticable, and that it might prove very useful.

MURDOCK'S LIQUID FOOD.

This widely advertised article of diet, which had for some time the *quasi* endorsement of certain well-known members of the medical profession in Boston, and which is said to still have the support of the *Annals of Gynecology*, has recently come in for a share of the searching investigations of that admirable paper, the *Boston Journal of Health*. The result has been a description of the character of Murdock's Liquid Food

which is not calculated to increase its popularity with the medical profession. The present state of the discussion includes statements by disinterested medical men that the manufacturer of this food has attempted to deceive the medical profession and the community, and denials and counter charges by Mr. Murdock. As it stands, the latter seems to have decidedly the worst of it; and our readers may as well bear in mind that the claims made for his preparation are discredited by those who probably know most about it and him, and that it is openly placed in the same category with fraudulent articles of commerce.

THE INDEX MEDICUS.

For some years past Mr. George S. Davis, of Detroit, has been publishing, at a pecuniary loss, the *Index Medicus*, which is a monthly periodical, containing a classified index of the titles and authors of papers and books on medical science, appearing from month to month. It is unfortunate that so important a work as this, and one so creditable to the United States, should be dependent upon private enterprise. It ought to be supported entirely by the funds of the Government, especially when this Government is groaning under the burden of a surplus of wealth, which seems to afflict it as much as the poverty of other governments afflicts them.

As it is, we appeal to as many of our readers as have scholarly tastes, to aid in maintaining the enterprise of the publisher of the *Index Medicus*, by forwarding their names and the subscription price—ten dollars a year—to Mr. Davis. Meanwhile we would urge upon them the advisability of trying to influence their representatives in Congress to make this important publication a part of the good work which the National Government is doing in other directions.

—A blind physician of Pensacola, Fla., has a large practice, and is able to find his way, unaided, about the principal streets of the town in a way that would not discredit that popular institution, the oldest inhabitant.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

VALOR DE LA CURA DE LISTER EN LAS HERIDAS CONTUSAS. Por D. Enrique de Areilza y Arregui, Médico-Director del Hospital de Triano (Viscaya). Tésis del Doctorado. Small quarto, paper, pp. 32. Bilbao, Typographia Católica de San Francisco de Sales, 1884. (Value of the Method of Lister in Contused Wounds, etc.)

In this interesting inaugural thesis Dr. Areilza argues that the essential character of contused wounds is the diminution or abolition of vitality in the injured parts, and a tendency to the development of putrefaction. For the control of this tendency the application of the principles of Lister's method is almost entirely useless; because the germs which cause such putrefactive changes may come from the interior of the body, and are not necessarily an invasion from without it.

The argument is carefully and elaborately arranged, and is of the most convincing character, being supported by a series of observations and experiments which leave little room for doubt that the opinions of Dr. Areilza are correct.

THIRTY-SEVENTH ANNUAL REPORT OF THE CINCINNATI HOSPITAL FOR THE YEAR ENDING DECEMBER 31, 1887. 8vo, paper, 80 pages. Cincinnati, 1888.

It is not usually desirable to comment upon the reports of hospitals, except when they are as elaborate as those of a few English and German institutions, and contain valuable papers by members of the medical staff. But we may make an exception in the case of the Cincinnati Hospital Report before us, because, in addition to the usual details of house-management it contains unusually well-prepared tables of statistics, and certain appendices of considerable value. One of the best of these is that attached to the medical report, which contains a brief but useful summary of the methods of treating typhoid fever by three of the physicians to the hospital.

It is a great pity that the abundant material of hospitals in every part of the world furnishes so little in the way of broad study of diseases and their treatment, and we wish that some way could be found by which each year should furnish some systematic study of large groups of cases by the medical officers of our American hospitals.

Pamphlet Notices.

[Any Reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage stamp.]

Igiene Sperimentale. Ancora sui Neutralizzanti del Virus Tubercolare. Nota del Socio Cav. Giuseppe Sormani, Pavia, Italy. From the *Rendironti del Regio Instituto Lombardo di Scienze*, Ser. II, Vol. XX, Fasc. XIX. 3 pp.

In this little pamphlet Prof. Sormani follows up his recent investigations in regard to the power of a number of chemical agents to destroy the activity of tuberculous virus. The experiments concerned

chiefly the ease and rapidity with which the different agents proved efficient in rendering tuberculous matter inert, and the results announced are interesting; although we do not at present see any very important practical application of them.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—The *Medical Investigator* is a monthly journal, edited and published by S. F. Smith, M.D., at Louisville, Ky. The first number is dated April, 1888, contains 24 octavo pages, and announces that the "subscripion (*sic*) price" is 50 cents a year. It is said to be devoted to medicine and temperance; but the main object seems to be to advocate total abstinence, and the dispensing of their own medicines by physicians. The literary merits of this new venture are not very great, and it does not bear the marks of very vigorous vitality.

Correspondence.

New Use for a State Board of Health.

Editor Med. and Surg. Reporter:

Sir:—An editorial in the last issue of the Reporter, under the heading: "A New Use for a State Board of Health," affords me an opportunity for publicly correcting a misstatement which has been the source of excessive annoyance to the Pennsylvania State Board of Health. The following is the explanation of the very objectionable placard in one of the lines of street passenger railway cars to which you call attention:

The *Annals of Hygiene*, which has been adopted by the Board as its official organ, has undertaken, on its own responsibility, a series of analyses of articles of food, including beverages. These analyses it has from time to time published, with comments on their results. Among the articles thus analyzed were several beers. The proprietor of the beer which showed the best result has taken advantage of the fact that the *Annals* is the official organ of the Board to announce that the Board commends his beer. The subject of beer has never been discussed by the Board. The Board has never authorized an analysis of beers. Perhaps it has been derelict in not doing so; but it conceived that other duties were more important and pressing. The moment that the advertisement referred to appeared in the cars, the secretary addressed an urgent remonstrance to the company against this unauthorized and misleading use of the name of the Board. The only result was the substitution of a second of even a more unwarrantable character than the first. The law is so little to be depended on in redressing a grievance of this kind, that the Board has so far considered it wiser not to appeal to it. It has trusted that the good sense of our citizens would lead them to the same conclusion at which you at once arrived—that "there must be some mistake about this."

Benjamin Lee, M.D.,
Sec. State Board of Health of Pennsylvania.
Philadelphia,
April 24, 1888.

[The mistake to which we referred and which our correspondent regrets, seems to be due to the fact that the State Board of Health of Pennsylvania does not exercise the supervision which it should over a publication which it permits to use its name. So long as the *Annals of Hygiene* is permitted to call itself the "Official Organ" of the State Board of Health, this body will naturally and properly be held responsible for its doings —Ed. Reporter.]

Membership of College of Physicians and County Society of Philadelphia.

Editor Med. and Surg. Reporter:

Sir:—Will you please tell me: 1, What are the qualifications for membership of the County Medical Society and of the College of Physicians? Also, 2, If the fact that a doctor dispenses his own medicine disqualifies him for membership in either?

And oblige, An Ignoramus.
Philadelphia,
April 20, 1888.

[1. *The College of Physicians.*—The Fellows of the College of Physicians of Philadelphia must be physicians, of good character and professional standing, residing within the city of Philadelphia, or within thirty miles thereof in the State of Pennsylvania, over twenty-four years of age, and graduates of at least five years' standing. Candidates for Fellowship must be proposed in writing by three Fellows; their application for Fellowship is referred to the Council of the College, and if approved by the Council, it is voted on by the College, after being read at three successive meetings. An election requires a four-fifths vote of the Fellows present and voting. Entrance fee, $25.00; annual dues, $15.00.

The Philadelphia County Medical Society.—Active members must be graduates of at least one year's standing of a regular medical school, and residents for not less than one year of the County of Philadelphia. Candidates for membership must be proposed in writing by three members, the proposition read at a meeting, referred to the Censors, referred back at the next meeting, and voted on at the meeting following this one. There is an initiation fee of $5.00, and persons elected before the June business meeting must also pay the regular annual dues of $4.00.

2. No! —Ed. Reporter.]

Use of Obstetric Forceps.

EDITOR MED. AND SURG. REPORTER:

Sir:—I would like to call attention to the remarks of Dr. Packard, REPORTER, March 17, 1888, page 337, in regard to the teaching of Dr. A. H. Smith in reference to the obstetric forceps. By referring to Vol. 3, Transactions of the American Gynecological Society, he will see that Dr. Smith *condemns* side to side movements. In Dr. Smith's lectures delivered in the summer of 1884 he strongly condemned lateral or rotatory movements with the forceps. Yours truly,

GEO. W. POTTS, M.D.

New Lancaster, Kan.,
April 18, 1888.

NOTES AND COMMENTS.

The Feeding of Children.

Not until three years old should a child be permitted to take its meals at the table. Parents should understand that even then he has not reached an age when a full diet can safely be allowed.

First of all, he must be taught to eat slowly, and parents certainly ought to set the example. The habit of "bolting" food, so common to many, both children and adults, is an extremely pernicious one, for which there is no excuse.

Even before this period, sound fruits may be allowed children, provided, of course, those easy of digestion are selected, and care is taken to remove the seeds, skins, etc. It will be well to encourage them, when they join the family at the table, to eat a small quantity of fruit for breakfast, and before other foods are served. For this meal, children may be allowed milk, oatmeal, bread and butter, and eggs, either lightly boiled, poached or scrambled. If, instead of eggs, they prefer fresh fish or steak, either one or the other may be given; the meat, of course, must be minced fine. Fried foods are forbidden, and this includes fritters and fried cakes.

At dinner, if the soup is thin, it may be allowed, but that kind of soup so often in the home of the laborer, and which is made from bones, thickened with vegetables, and strongly flavored with onions, is entirely unsuited to a child's digestion, and should never be given it. Roast or boiled meats, such as beef or mutton, may be allowed; the fact that pork and all salted and otherwise cured meats are difficult of digestion should be remembered, and their indulgence forbidden.

Potatoes, baked or boiled, dry and mashed, spinach and peas, string beans, asparagus of good quality, cauliflower, and beets when young, are no burden to a child's digestion, and should be allowed; with green corn it is different, unless that which is very tender is used, and the kernels are carefully crushed or grated. Such vegetables as turnips, cabbage, carrots, parsnips and onions, require strong powers to digest them. The same may be said of celery, unless it is stewed. While the vegetables which have been recommended as a part of children's dietary are usually well borne by them, it must not be assumed that they can safely eat them all at one meal; only two of them should be partaken of each day.

For supper, milk toast, bread and butter, and a glass of milk, with possibly a little stewed fruit, will be quite sufficient for young children. Hot bread, cheese and hashed meat and vegetables, so often the supper of the hearty workman, is altogether too indigestible for young children. In fact, it should be the duty of the mother to learn what foods are easily digestible, and none others should be allowed. Her own powers of digestion, or those of the father, cannot by any means be considered a safe guide in the selection of food for her little one.—*Boston Journal of Health*, March, 1888.

Fatal Effect of Christian Science.

The Philadelphia *Evening Telegraph*, April 21, reports that the town of Medford, Mass., is excited over the death of a Mrs. A. James and her new-born child on April 20. Mrs. Connor, the mother of Mrs. James, practices the cure of diseases by prayer or by the method of a Christian scientist. The husband of the dead woman was away from home on business, and it appears that no midwife or physician, other than Mrs. Connor, was called, until both mother and child were dead. Dr. J. L. Coffin was summoned, and, after inquiring into the facts, insisted upon having an autopsy. The town physician, who assisted in the autopsy, states that it showed that mother and child were perfectly healthy before their decease, and that, with the care she should have been given by a common nurse, both would have been alive. It is probable that Medical Examiner Durell will institute legal proceedings against Mrs. Connor.

Contrast between Strychnine and Alcohol.

Dr. Jaroshevsky has instituted experiments upon dogs with regard to the contrast between strychnine and alcohol, and has

come to the following conclusions: 1. Strychnine neutralizes the narcotic and toxic actions of alcohol. 2. With the addition of strychnine, large doses of alcohol may be taken for a pretty long time without the appearance of those changes in the organs which occur after the use of alcohol. 3. Strychnine should be given in all forms of alcoholism. 4. Strychnine may be considered as a powerful prophylactic agent against alcoholism.—*Deutsche med. Wochenschrift*, March 13, 1888.

Poisoning from a Belladonna Plaster.

Dr. J. E. Horn, in a letter to the *Cincinnati Lancet-Clinic*, March 31, 1888, states that for a painful arm he applied a belladonna plaster to relieve the soreness; the plaster was four by eight inches in size. It was on about thirty hours, and because of the burning it produced the patient removed it, and a vesicated spot the size of the plaster was visible. Two days later he was called in, and on looking at the arm was frightened to find the denuded surface of a deep, angry red, and a scarlet hue extending from its edges in every direction. The arm was swollen all the skin would admit of from shoulder to elbow, even extending to the fingers and hand, but not so great below the elbow. The patient complained of dryness of the throat, and had double vision. The inflammation remained about in the same condition for three days, and then began to gradually subside. The patient told him that she was served nearly the same way years ago, when another physician had applied a "plaster." She also said that turpentine or coal oil would blister her in a few minutes if applied to the skin.

Care of the Pauper Insane.

It is reported from Albany, N. Y., under date of April 13, that the Assembly has passed an Act, by a vote of 77 to 7, authorizing the Overseer of the Poor of Ulster County to remove to that county for its keeping any indigent chronic insane it may have in any State insane asylum.

The act was strongly opposed by several members of the Legislature, as a backward step in the method of providing for the indigent insane.

Polydactylitis.

In Oerebro, Sweden, a shoemaker and his son have on both their hands two thumbs each, which are fit for work. This surplus of fingers is present also in a brother of the shoemaker and in four of his children, but in these five persons the supernumerary finger is not capable of work. The mother of both the brothers has six toes. No such peculiarity has been reported concerning the grandmother on the mother's side; but the great grandmother is known with certainty to have been supplied with six fingers on each hand. This deformity has therefore been transmitted through five generations.—*Allgemeine med. Central-Zeitung*, Feb. 11, 1888.

Acid Bichloride Solution.

Prof. Krönlein, of Zürich, communicates the following formula for an acid solution of corrosive sublimate with salt, to the *Correspondenz-Blatt für Schw. Aerzte*, No. 4, 1888:

Hydrarg. bichlor. cor.	16 oz.
Sodii chloridi,	
Acid. acetici dil (20.4 %) of each	8 oz.
Aquæ	32 oz.

M. Sig.—10 % corrosive sublimate solution.

This concentrated solution is kept on hand in the shops and clinics, marked with the word poison, in order to quickly prepare the customary $\frac{1}{20}$ to $\frac{1}{10}$ per cent. solutions for surgical purposes. According to Meyer, of Göttingen, it remains clear both in the dark and light, and forms no basic precipitate with strong lime water even after being kept for months.

Puerperal Eclampsia.

Dr. William Goodell in a letter to the *Medical Standard*, April, 1888, says: "In the majority of cases of puerperal eclampsia, I limit my treatment to chloral hydrate thrown up the bowel. This is repeated whenever twitchings or other premonitory symptoms of recurring convulsions manifest themselves. In plethoric cases I bleed first and then give chloral hydrate per rectum. Whenever convulsions are threatened I either bleed or else give chloral hydrate per os in smaller doses until headache is relieved or until the twitching, double vision or blindness are removed. If labor has begun, I give chloroform, not ether, and deliver rapidly. If labor has not begun, I watch and await events, interfering only when compelled."

Prescription for Headache.

Dujardin-Beaumetz recommends the following:

℞	Caffeine	gr. iv
	Salicylate of sodium	gr. iv
	Hydrochlorate of cocaine	gr. iss
	Water	f℥ij
	Syrup	f℥vss

M. Take the whole at one dose at the beginning of the attack.

Salol as an Antiseptic.

Just as antipyrin after its original applications was found to have numerous others equally effective, so it is now with salol, which seems likely therefore to presently command a more extensive patronage. One of these seems to be really important. The antiseptic properties of the compound have always been recognized, but salol has never been applied externally. Now, however, continuing the parallel with antipyrin—the most important property of which was discovered in a country other than that in which it was first used—salol has been proved to be a valuable antiseptic in France, Italy, and Switzerland. It is specially recommended as a substitute for iodoform, in all cases in which the latter has been previously used, and considering its freedom from objectionable odor, it is not astonishing that its application in this direction should find favor. Moreover, it is not toxic, which is more or less the case with iodoform. Another advantage is that it is about twenty per cent. cheaper than iodoform.—*Chemist and Druggist*, March 24, 1888.

Lafayette Mixture.

The Lafayette mixture as recommended by Bumstead (1870) is as follows:

℞ Copaibæ ..... f ʒ j
Liq. potassæ ..... f ʒ ij
Ext. glycyrrhizæ ..... ʒ ss
Spir. æth. nitrosi ..... f ʒ j
Syrupi acaciæ ..... f ʒ vj
Olei gaultheriæ ..... gtt. xvj

Mix the copaiba and the liquor potassæ, and the extract of licorice and sweet spirit of nitre first separately, and then add the other ingredients.

Dose.—A tablespoonful after each meal.

Dr. Keyes's modification of this formula is as follows:

℞ Potassæ citratis ..... ʒ ij–vj
Bals. copaibæ ..... f ʒ iij–vj
Ext. hyoscyami fl ..... f ʒ ss–ij
Syr. aciaciæ ..... f ʒ iss
Aquæ menth. pip. q.s. ad. f ʒ iij

M. Sig.—Shake. Teaspoonful in water.

Formula for Tobacco Amblyopia.

A. St. Clair Buxton says (*Lancet*, Feb. 25, 1888), that the following formulæ have proved useful in this affection:

Liq. hydrarg. perchlor. (B. P.) . . f ʒ ss
Potassii iodidi ..... gr. xij
Aquæ destil. ad ..... f ʒ j

Sig.—Take three times a day.

Ext. nucis vom. ..... gr. ss
Ext. hyoscyam ..... gr. j

Ft. pil. No. j. Take with each dose of the mixture.

Amylene Hydrate.

The testimony as to the good effect of amylene hydrate as a hypnotic continues to grow. Georg Buschan has a good word for it in the *Beliner klin. Wochenschrift*, March 19, 1888. He thinks that amylene hydrate, although not a hypnotic of the first rank, is a substitute for chloral and paraldehyde, possessing the preference over the former in not being in so great a degree a cardiac depressant, and over the latter on account of better action with smaller doses, and also because it lacks the unpleasant odor exhaled from patients taking paraldehyde. He thinks it should be used in general medical practice, and reports success from its hypodermic use.

Antifebrin.

Dr. E. Houston, of Stanberry, Mo., writes to the *Weekly Medical Review*, April 7, 1888, that he has obtained excellent results from the use of antifebrin in inflammatory rheumatism, neuralgias, and as a hypnotic in insomnia due to reflex nervous phenomena in women. He has also given it in cases in which the extremities were cold and bathed in clammy sweat, temperature below normal, and heart embarrassed. These symptoms, he says, disappeared in an hour. He regards it as a heart tonic.

Successful Case of Cæsarean Section.

Dr. Howard A. Kelly, of Philadelphia, did the improved Cæsarean operation, April 17, 1888. The patient was a dwarf, fifty-two inches in height. The indication for the operation was absolute, as the patient had a generally contracted pelvis with a true conjugate estimated at 2¼ inches. The woman had been in labor nine days, and the membranes ruptured four days, before Dr. Kelly was called. The whole operation occupied thirty-seven minutes, the delivery of the child, five minutes. The patient is doing well, eating heartily, with a pulse of seventy. The child died of jaundice at the end of a week. Should this woman recover, and there is every reason to believe she will, it will be the first recovery under Cæsarean section in Philadelphia in half a century.

The Sense of Taste.

Science, March 23, 1888, contains an interesting paper by E. H. S. Bailey, and E. L. Nichols, on the delicacy of the sense of taste. These investigators found, by experimentation, that men detected one part of quinine in 392,000 parts of solvent, women one part in 456,000; men detected one part of acid in 2,080, women one part in 3,280;

men detected one part of salt in 2,240, women one part in 1,980; men detected one part of sugar in 199 parts, women one part in 204; men detected one part of soda in 98 parts, women one part in 126.

From these results the following conclusions may be drawn:

1. The sense of taste is much more delicate for bitter substances than for any others. It is possible to detect quinine in a solution which is only $\frac{1}{2000}$ the strength of a sugar solution—and quinine is only $\frac{1}{10}$ as bitter as strychnine.

2. The order of delicacy is, bitter, acid, salt, sugar, and alkali.

3. The sense of taste appears to be more delicate in women than in men. This is true in the case of all the substances except salt. A similar difference was found in favor of female observers in an earlier and independent set of experiments, which agreed in every essential particular with the results of the present test.

Marked differences in the delicacy of the sense of taste of different individuals were met with in the course of these experiments. There were persons who could place in the proper class, solutions containing one part of quinine in 500,000, and other substances in corresponding high dilution, while some failed to detect solutions of more than three times the above strength. Among the men examined were many who have been accustomed to handling and recognizing drugs and medicines, and yet even these were frequently surpassed by female observers who had no such training.

In a few cases, the ability to detect a dilute sweet was accompanied by a lack of ability to detect dilute bitters. This peculiarity was, however, far from being a general one. Among the observers subjected to experiment, the frequent use or disuse of quinine seemed to have had no special influence as effecting its detection.

As to the degree of delicacy of the human sense of taste for the substances in question, there is reason to believe that they are but slightly influenced by individual idiosyncrasies, and may be regarded as fairly representative.

Pennsylvania State Medical Society.

The Pennsylvania and the Philadelphia and Reading railroads and their branches will sell excursion tickets for the session of the Medical Society of the State of Pennsylvania in Philadelphia in June next. Application for an order, naming which road, may be made to Dr. Wm. B. Atkinson, 1400 Pine Street, Philadelphia. Tickets will be sold for one-third less than the usual rate.

NEWS.

—Dr. George M. Gould has removed to 119 South Seventeenth street, Philadelphia.

—Dr. Clara Marshall has removed to 131 South Eighteenth street, Philadelphia.

—According to a provision in the Budget presented by the Chancellor of the Exchequer to Parliament, English physicians are threatened with a tax of five dollars on their horses.

—The *British Medical Journal*, April 21, 1888, announces the death of Dr. De Chaumont, who succeeded the late Professor Parkes in the chair of Military Hygiene, at the Royal Army School, England.

—Since the first of January there have been 78 cases of small-pox reported in Philadelphia. Of this number 42 were sent to the Municipal Hospital, and eleven died. The number of cases is diminishing.

—Governor Beaver has appointed a commission, under the act of June 14, 1887, to select a site and erect thereon a hospital, at or near Hazleton, Penna., for injured persons in the middle coal fields. An appropriation of $60,000 has been made for the purpose.

—Dr. R. B. Root reports to the *Boston Med. and Surg. Journal*, April 19, 1888, that he recently attended in confinement a young woman, 15 years old, whose great-great-great-grandmother is still living at the great age of 95 years, so that six generations of the family are now alive.

—The Marshall Hall prize has been awarded to Walter Holbrook Gaskell, F.R.S., Lecturer in Advanced Physiology in the University of Cambridge. This prize is given every five years for the best original work done during that period in physiological or pathological research.

—The next meeting of the American Gynecological Society will be held in Washington, September 18, 19 and 20, in order to give the members of the society an opportunity to attend the sessions of the Congress of American Physicians and Surgeons, which is to be held in Washington at that time.

—The *Northwestern Lancet*, April 15, 1888, says that in the vomiting of early pregnancy, lying with the shoulders low and the hips elevated will give quick relief. A linen compress saturated with French brandy, strapped tightly over the gastric region with adhesive plaster, acts mechanically in holding the muscles quiet, and will sometimes do wonders in these cases.

HUMOR.

INDIGNANT PHYSICIAN: "Man, what have you done? You sent my patient the wrong prescription, and it killed him."

Druggist (a calm man, accustomed to abuse): "Vhell, vhat vas der madder mit you? Last veek I send your odder patient der righd berscription, and dot killed him. How can somebody blease sooch a man?"—*Brooklyn Eagle.*

STRANGER (in drug store): "You seem to carry an extensive line of goods."

Proprietor (affably): "Yes, sir."

"I've been told that you are a reliable man to deal with."

"You will find everything just as represented, sir. What can I have the pleasure of doing for you?"

"I guess I'll take a look at the directory."—*Judge.*

IN AN ITALIAN JOURNAL, *Il Giornale delle due Sicilie*, there was, not long ago, a translation of a paragraph in an English newspaper, giving an account of a man having beaten his wife with a poker. The word "poker" was not intelligible to the editor. He, however, had the candor to admit his ignorance, which he did in the following language: "Non sappiamo, per certo, se questo 'pokero' Inglese sia uno strumento domestico o bensi chirurgico"—"We do not know with certainty whether the English poker be a domestic or surgical instrument."—*N. Y. Evening Post.*

JAMES PAYN, THE NOVELIST, is editor of the *Cornhill Magazine*, London. Next door to his office a medical journal has its sanctum. One day Mr. Payn's door was cautiously opened and a pale-faced, long-haired individual entered. "I have brought a little thing about sarcoma and carcinoma," said the visitor. "Very sorry, sir," said Payn, politely, "but we have all the poetry we want." "This isn't poetry!" exclaimed the visitor. "It is an essay on two varieties of tumor." "Oh, I beg your pardon," said Payn, "I thought they were a pair of Italian lovers." The long-haired man was a well-known professor who had entered the wrong office.

OBITUARIES.

ANDREW B. VAN HORNE, M.D.

Dr. Andrew B. Van Horne died at Orange, N. J., March 31, of pulmonary phthisis. He was graduated from the College of Physicians and Surgeons, New York, in 1880, and not long afterwards was obliged to go to Colorado Springs for the sake of his health, and returned from there only last summer.

THOMAS D. WORDEN, M.D.

Dr. Thomas D. Worden, of Wilkesbarre, Pa., died in Fort Plain, N. Y., April 19, 1888, at the age of 34 years. He was a graduate of Albany, N. Y., Medical College. The last year of his life was spent in Colorado Springs, Colorado, where he went thinking that the climate would be beneficial, suffering as he did from lung trouble. His disease, however, resulted in his death, two weeks after returning to the East.

EDWARD GREELY LORING, M.D.

Dr. Loring died suddenly in New York, April 23, in the fiftieth year of his age. On the day of his death he attended to his practice as usual. It is understood that his sudden death was owing to heart disease, though no such affection was known to his friends, and probably not to himself.

Dr. Loring was graduated from the Medical Department of Harvard University, in 1864. He soon came to New York, and for a time was associated in practice with the late Dr. Agnew. At the time of his death, and for many years before, Dr. Loring was one of the surgeons of the New York Eye and Ear Infirmary. He was widely known and generally recognized as an authority upon ophthalmoscopy. His "Text-book of Ophthalmoscopy," the first volume of which was published in 1886, took rank at once as the standard American work on that subject. His death is the more to be deplored as it follows so closely upon that of Dr. C. R. Agnew, and so makes two notable vacancies in the ranks of New York ophthalmologists.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the two weeks ended April 21, 1888:

W. H. H. Hutton, Surgeon, to proceed to Biloxi, Miss., on special duty, April 21, 1888.

W. H. Long, Surgeon, granted leave of absence for fourteen days, April 21, 1888.

H. W. Sawtelle, Surgeon, granted leave of absence for seven days, April 21, 1888.

F. M. Urquhart, Passed Assistant Surgeon, granted leave of absence for seven days, April 10, 1888; to assume temporary charge of Cape Charles Quarantine Station, April 17, 1888.

J. H. White, Passed Assistant Surgeon, relieved from quarantine duties at Sapelo Station, April 21, 1888.

L. L. Williams, Passed Assistant Surgeon, relieved from duty at Marine Hospital, Boston, Mass.; to assume charge of Cape Charles Quarantine Station, April 17, 1888.

W. D. Bratton, Passed Assistant Surgeon, relieved from duty at Marine Hospital, San Francisco, Cal.; detailed as medical officer, Revenue Steamer "Bear," during Summer cruise, April 19, 1888.

Changes in the Medical Corps of the U. S. Navy for the week ending April 28, 1888.

Medical Inspector A. S. Oberly granted six months' leave, with permission to visit Europe.

WHOLE No. 1628.] MAY 12, 1888. [VOL. LVIII, No. 19.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session in addition to four Didactic lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars see annual announcements and catalogue, for which, address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

CLEARING OUT SALE

—OF—

POCKET RECORDS.

We have on hand a small number of Pocket-Records prepared for the year 1887.

We would like to sell them, and in order to get rid of them, we will make the following offer; we will mail

A Pocket-Record for 30 Patients a week for 50 cents.
" " 60 " " 75 "

This is Less than the Books Cost Us.

There is nothing the matter with them, but we want to clear them out.

Drs. RANDOLPH & DULLES.

MEDICAL AND SURGICAL REPORTER

No. 1628. PHILADELPHIA, MAY 12, 1888. Vol. LVIII.—No. 19.

Communications.

THE APPENDIX VERMIFORMIS; ITS FUNCTIONS, AND PATHOLOGICAL CHANGES AND THEIR TREATMENT.[1]

BY J. M'FADDEN GASTON, M. D.,
PROFESSOR OF SURGERY, SOUTHERN MEDICAL COLLEGE, ATLANTA, GA.

Preliminary to a consideration of the functions pertaining to any organ, it is requisite to understand its structure, or in other words the physiology of a part depends upon its anatomy. The presence of the appendix vermiformis in man and in some of the higher orders of apes, while it is absent in quadrupeds and other inferior animals, may perhaps lead the followers of Darwin to the conclusion that the missing link is to be sought in this development; but I have no inclination to enter into the abstruse questions of evolution, and only regret that we are precluded from receiving any information from a study of comparative anatomy in respect to this unique appendage. If the dog and cat were supplied with this structure, the facility for making experiments upon them might enhance very much our knowledge of its normal and abnormal conditions, whether idiopathic or traumatic; but the door is shut to all such investigation, and the human subject does not fully avail for satisfactory data in regard to its structure and its office. In its general outline the appendix is subject to great variations of size and position, being found in different subjects from three to six inches in length, and lying diversely in its relation to the cæcum. Its diameter admits of considerable changes owing to the variable contents of the canal, whether gaseous, mucous or serous. This tube is of the same size from its attachment to the lower wall of the cæcum to its termination in a blind pouch at its free extremity; and when empty or occupied only with mucus this measurement is ordinarily about one-fourth of an inch. There is usually a mesenteric attachment to the wall of the cæcum, and this duplicature of the peritoneum invests its entire length, while a muscular layer is found between this and the mucous membrane which lines it. The opening into the cæcal cavity has a valvular arrangement of the mucous membrane which is capable of closing the orifice, and doubtless ordinarily prevents the entrance of foreign bodies into this blind pouch. It becomes dilated, however, under certain circumstances so as to admit of the passage of small solid masses through this orifice, and these become arrested in the tube and prove a source of disturbance. In view of this fact, this valve has been regarded by some writers as a trap, which is very prone to cause obstruction of the canal of the appendix by foreign bodies, as when the latter are once introduced there is perhaps a kind of constriction of the orifice of the appendix which interferes with their escape. That there exist in the middle coat of the appendix longitudinal and circular muscular fibres, which by their alternate contraction and relaxation provide for a serous or mucous exudation, and after certain modifications in it promote its expulsion, is very evident from a study of the histological elements of its organization. Whether or not any considerable proportion of fæcal matter enters the cavity of the appendix has not been determined, but it seems most probable that the quantity must be small in view of the relative size of this diminutive tubular sac and the capacious cæcal

[1] Read in the Surgical Section of the American Medical Association at the meeting in Cincinnati, May 8, 1838

pouch which receives the contents of the ileum through the ileo-cæcal valve. The capacity for distension being limited in extent, precludes the view that the cavity of the appendix may serve as a diverticulum in cases of undue accumulation of fæcal matter in the colon. An opportunity has been recently afforded me of noting that obstruction of the descending colon from an organic stricture, inducing such distension of its walls by the retained contents as to result in perforation and death, did not materially affect the size of the appendix vermiformis. It cannot, therefore, be regarded as a safety-valve for the cæcum, but is rather to be looked upon as a loop-hole for the entrance of matters prejudicial to it and the adjacent structures; and may be appropriately regarded as a danger signal to warn the organism of approaching trouble.

The location of the orifice of the vermiform appendix at the most dependent part of the caput coli, while the entrance of the ileum through the ileo-cæcal valve is above and at the inner side, affording a direct passage to the contents of the alimentary canal into the cæcum as a receptacle, would seem to favor the conclusion that some change is there brought about by the contact of fæcal matter with the discharges from the appendix.

Its mucous lining, according to Gray, is furnished with a large number of solitary glands, and Satterthwaite states in his "Manual of Histology" that "in the vermiform appendix we find the collection of solitary lymph follicles so closely placed that the space left between adjoining glands does not equal in diameter that of these structures themselves."

On the other hand, we learn from Quain that "in man the chief function of the cæcum is absorption, as is shown by the great number of lymphatics in its walls;" while Landois tells us that "the contents assume the characters of fæces and become formed in the lower part of the great intestine." The high authority of Littré warrants the assertion that "it is in the cæcum that the residue of the alimentary substances assumes all the characteristics of fæcal matter;" and in the absence of other explanation of the peculiar odor imparted to the contents of the colon from this point forward, it is fair to infer that this modification comes from the influence of the appendix vermiformis, either by some chemical or vital process.

I have not such data to hand in support of this view as will stand the test of scientific criticism. Notwithstanding the fact that I am without material for vivisection, in the absence of wombats and apes, while the opportunities for elucidation from observations upon the human body are few, yet upon the principle of exclusion it is expected that this theory of the function of the appendix may be entitled to consideration. As its province in the animal economy has not heretofore been pointed out by physiologists, I would appeal to them to recognize this hypothesis, on the same basis that the owner of a certain historic dog in the backwoods of North Carolina claimed that he was a good "'possum dog,"—that he had tried him thoroughly for every other species of game without discovering any hunting qualities, and hence he concluded that he ought to be good to catch the opossum. Reasoning upon the general principle that all the organs of the human body are fitted for the discharge of a useful end in the animal organism, we are not warranted in concluding that the appendix vermiformis is an exception to this rule of the fitness of things, and it behooves us to investigate seriously its function. We should satisfy ourselves as to its relations to the digestive and excrementitious processes, with its position as a sentinel at the gateway, without participating, so far as is known, in the work of alimentation or defecation.

The antiseptic property of sulphurous gases is well known, and the presence of sulphuretted hydrogen in the colon cannot be accounted for by any process of decomposition developed in its contents, as the cases of arrest of fæcal matter, with or without impaction, are not attended with such results as would ensue from such a process. We are therefore warranted in attributing the absence of any signs of degeneration to the presence of an antiseptic element, which is developed in the vermiform appendix and intermingled with the fæcal mass in the cæcum, which serves as a reservoir where this process may be undergone as the residue of the alimentary substances is poured out of the small intestines. The effectual security against regurgitation afforded by the construction of the ileo-cæcal valve, as well as the barrier formed by the valvular opening of the appendix, which prevents the entrance of fæcal matter into its cavity, while gaseous emanations or its natural secretion of mucus may pass out into the caput coli—these facts favor the view that an important office belongs to the appendix vermiformis in preserving the contents from decomposition during their progress through the colon, an office beyond that claimed for the admixture of the bile elements with the excrement. It

is evident that ordinarily the fæces do not enter the canal of the appendix, owing to the nature of the duplicature at its orifice, and when by failure of this impediment, solid matters, fæcal or otherwise, do enter its cavity, there is no capacity in its walls for their expulsion. It therefore follows that in case of such accidents an inflammatory process is developed in the appendix. The number of cases in which the appendix has been removed by operative procedures, or has been obliterated by disease, are thus far comparatively few, and the observations upon the effects of such loss have not been reported in such a way as to throw any light upon the function of this development which characterizes a higher order of animal creation. The vague conception that the appendix is rudimentary in nature seems to have taken possession of physiologists without any show of reason or any foundation in fact, so far as the study of comparative anatomy can aid in directing us to a satisfactory conclusion. If it can be made to appear that the native population of our primeval forests, which subsisted largely upon herbs and roots, with an admixture of animal food, presented any marked increase of development in this respect, it might go towards sustaining this claim. But this hypothesis is far-fetched, and I am not aware of any such facts to corroborate it, nor are there any data available from the history of the human race since the creation of mankind, which tend towards a confirmation of this view; and the attempt to bolster up a theory without facts is only an acknowledgment of utter ignorance.

The increased number of disorders of the appendix vermiformis which have been recognized in these latter years might lead to an inference that it is destined to entire obliteration in the course of time, were it not evident that many affections of the appendix were formerly ignored from the lack of proper observation in diagnosticating the troubles of this region. Should it appear in the future that the appendix vermiformis may be removed with impunity, then it will only prove what has been demonstrated in the case of other important members of the body, namely, that they are not essential to the human organism. But no one would undertake to set aside the important office of the ovaries in the *rôle* of creation, because, forsooth, they have been removed without detriment to the subsequent health and comfort of the individual. It strikes me forcibly that the practice of oöphorectomy resorted to so frequently of late for slight causes, and in some instances without indications of disease in the organ, may at no distant day be held as an excuse for cutting down upon the vermiform appendix on the slightest provocation, for the purpose of ligating and excising it, and thus ridding the individual of further trouble from its disorders. How far this might be justified from a consideration of the great risk to life attending inflammation and perforation of its walls, depends, in the absence of trustworthy data for an early diagnosis, upon the importance which may be attached to the function of this peculiar structure, after further observation of the effects of its removal; and surgeons must await the result with interest.

Whether inflammation is developed in this structure independent of mechanical irritation from the entrance of foreign bodies or the formation of fæcal concretions, has not been clearly demonstrated. Clinical observation in cases which yield to treatment leave doubts as to the real seat of the disease referred to this region, and so far as noted in *post-mortem* examination the lesions have for the most part been referred to the presence of a mechanical irritant. While some have asserted that inflammation is set up in the vermiform appendage as a result of derangement of the digestive apparatus, and others have supposed that the entrance of germs into its cavity has developed morbid processes in its structure, the facts go to prove that such causes of disease are rare in comparison with the troubles growing out of local irritation of a mechanical origin. It is remarkable that the presence of such foreign bodies rarely produces any serious inconvenience until perforation of the wall of the appendix ensues, and even then the localization of the pain and inflammation is not well defined, either by the sensations of the patient or by objective symptoms recognized in a physical examination by the practitioner. There is an absence of preliminary indications pointing to the nature of the inflammatory process at the incipiency of the disorders of the appendix vermiformis, which presents to the surgeon a problem difficult of solution.

At this early stage there may, however, exist a certain degree of sensitiveness upon pressure immediately over the site of the appendix, and this tenderness, revealed by cautious palpation, may serve for the recognition of an incipient inflammation in the appendix, when as yet there is no perceptible thickening or induration of the tissues. It is clear that the effects of the causative influence, of

whatever character it may be, must, up to a certain point, be of gradual operation in the development of inflammation. During this stage it is of the greatest importance to be able to recognize its progress, and not only should the external examination be carefully made, but the digital exploration by the rectum should also be directed to the discovery of the seat of the inflammation in the appendix.

There are in most instances some concomitants of the local trouble manifested in the derangement of the alimentery canal, perhaps of a reflex order, prior to the extension of the inflammatory process to the adjoining structures. In the early history of appendicitis, it has been noted that there may occur either a disposition to frequent evacuations or a state of intestinal torpidity, in which it is difficult to arouse the peristaltic action of the bowels either by purgative medicines or enemata. During this period the constitutional disturbance is not very marked, and yet there exists usually a febrile state, with slight rise of temperature, so that nice discrimination will detect a departure from the normal condition of the general system. While the presence of fæcal concretions or other foreign bodies in the canal of the appendix may be tolerated for a greater or less period without any manifestion of trouble in the ordinary performance of the functions of the intestines, there are good and sufficient grounds for the conclusion that intestinal derangement from other sources may become an exciting cause of developing the inflammatory process from the local irritant. The history of cases in which death has occurred from other diseases, present quite a number of instances in which there were unmistakable indications of disease of the appendix which had terminated by resolution. But it is generally found that inflammation set up in the wall of the canal from a mechanical irritant, leads to perforation and extravasation of the contents, accompanied by characteristic shock immediately, and followed by diffused inflammation. This is the dividing line between two distinct phases of symptoms, and whatever may have obscured the case previously, it is for the most part well defined after this grave result. There may be only a circumscribed involvement of the surrounding structures, exciting adhesive inflammation in the serous tissues which shut in the exudation from the cavity of the appendix, thus forming a local abscess. But usually the septic matter permeates in different directions and sets up general peritonitis, with a train of constitutional troubles, attended with marked cerebral disturbance and vital depression.

An observation of a peculiar pain in the penis from the perforation of the vermiform appendage has been reported by Tiffany, and the same marked feature occurred in my two cases of perforation which were verified by *post-mortem* examinations. In the elaborate paper of Fitz on Perforating Inflammation of the Vermiform Appendix, some stress is laid upon the disturbance of the urinary and genital organs. During the first three days following the onset of the pain connected with perforation, micturition is occasionally disturbed. Perhaps unusually frequent on the first day, it is likely to be difficult on or after the third day. In certain instances the use of the catheter is required. The right testicle may be retracted and swollen, in which case the course of the pain is apt to be toward this gland. We can understand how the escape of irritating matter from the appendix should cause trouble by transmitting inflammation to the contents of the abdomen, including the pelvic viscera, but it is not apparent that such disturbance of the urinary and genital organs results from general peritonitis induced by other causes, and the pain in the penis cannot be attributed to the peritonitis. If it should be found that this painful development in the penis is present in the early period of appendicular inflammation, and is not a result of perforation, it would aid very much in making the diagnosis at this stage.

We have the authority of a standard work on pathological anatomy and histology for stating that the most frequent form of inflammation of the appendix is a suppurative one. The appendix is swollen and congested; its walls are infiltrated with pus; at some points there may be necrosis and sloughing of portions of its walls. Within the cavity of the appendix we find fæcal concretions or foreign bodies, or nothing (but mucus). Such an inflammation may terminate in resolution, but more frequently it sets up an inflammation of the surrounding tissues. This inflammation may be either a local or general peritonitis or a suppurative inflammation of the parts about the appendix. Less frequently there is a chronic inflammation of the mucous membrane of the appendix, followed by constriction of its upper portion, while the lower part is dilated into a cyst filled with mucus and serum. (Delafield and Prudden.)

Another elaborate treatise on Pathological Anatomy and Pathogenesis, states that typhlitis and perityphlitis imply inflammation of the vermiform appendage and parts around it.

The vermiform appendix is peculiarly adapted to catch and retain substances pass-

ing through the cæcum. Matters which have been swallowed—such as grape-seeds, apple-pips, cherry-stones, and the like—and fæces, may accumulate in the appendage and set up inflammation. Sometimes these become crusted over with phosphates and carbonates, and so form fæcal concretions or calculi. The inflammation thus set up may extend to all the coats of the appendage, and then attack the contiguous structures, and in this way necrosis and gangrene, with perforation, may be caused. The issue differs in different cases. It is comparatively favorable if the inflammation continues to be circumscribed, while the exudation is moderate in amount; protective adhesions and false membranes may thus be formed about the affected spot. It is very unfavorable when perforation takes place before adequate adhesions are formed; fatal peritonitis is nearly always induced. When perforation takes place into a part of the peritoneum shut off by adhesions, a burrowing fæcal abscess is produced, which may burst internally or externally. Sometimes the appendage is entirely obliterated by adhesive inflammation; but if the inner or intestinal end becomes closed while the remainder continues to be patent, the natural mucous secretion may collect in the latter and distend it into a cyst. It is likewise specially noted that tuberculous and typhoid ulceration, localized in the vermiform appendage, may give rise to dangerous lesions. (Ziegler).

It is not out of place to repeat what has been stated by me in another recent publication, that I cannot acquiesce in that view of pathologists which attributes the degeneration of the cæcum and appendix to a low state of vitality in their tissues, but on the contrary I hold that they are highly vitalized, and that it is from being overtaxed in the performance of functions essential to the discharge of the excrement, that they are so subject to disease. I agree with Agnew in considering inflammation as hypernutrition, and consider that it is an effort of nature to restore the equilibrium of the circulation which has been interrupted by a local morbific impression from the causative agent. This inflammatory process is an attempt at recuperation of the injured part, and within certain limits it is salutary; but when it transcends the powers and capacities of the organism, I infer that from the undue excitation and over-action of this extraordinary impulse there is a breaking down of the forces of the organization, which leads to disintegration and death of the structures involved. By the development of inflammation in the tissues of the cæcal region, nature is resenting an insult to the components of this organ, and when it triumphs over the difficulties encountered, resolution ensues; but if it fails, there is ulceration and perforation, leading to abscess and peritonitis. To illustrate the important vital connection of the ileo-cæcal structure with the general organism, I may refer to the fatal results of the resection of this division of the intestinal canal in dogs, reported in my paper in *Gaillards Journal* on Obscure Impediments of the Intestinal Canal, while resection of a portion of the ileum was followed by complete restoration of the intestines. These deaths occurred in less than twenty-four hours, indicating that they were the effect of shock, which can be explained only upon the basis of a most intimate association of this structure with the organic nervous system.

Being therefore convinced of the traumatic reaction on the part of the cæcal division of the intestines as a consequence of injuries or morbific impressions, I would urge a prompt recourse to curative measures.

In regard to the procedure for the treatment of the diseased appendix, all writers are pretty well agreed upon using anodynes and keeping the patient at rest in the early stage with soothing fomentations over the iliac region; but some have resorted to a mild purgation or to an enema to secure evacuations, when the bowels are bound at the outset, and afterwards use opiates in full doses continuously. It may be put down as a dogma in the management of incipient cases of appendicitis that perturbation of every kind is hurtful, and that masterly inactivity should be observed with a view to promote resolution of the inflammatory process if this be possible, thus averting suppuration and perforation. With the uncertainty which hangs over the diagnosis in the early stage of appendicular disorder, the expectant treatment is generally recognized as the most prudent course, but there is a growing tendency among surgeons to cut the Gordian knot by a decisive step, and use an exploratory operation by incision for determining the exact seat and character of the disturbance. Aggressive practitioners, such as Bull and Weir, with others, have inculcated surgical interference at the earliest practicable period, and with the lights before us in cases of this kind the surgeon is warranted, so soon as he has good and sufficient reason to believe that there exists progressive inflammation of the appendix, in verifying this diagnosis by cutting down upon it. This course is indicated when the

symptoms of a local and constitutional or general nature are such as to raise a presumption in favor of appendicular inflammation, in advance of those phenomena which usually accompany perforation. In other words, an exploratory operation is advisable with a view of learning the exact condition of the parts involved. In the event of finding no evidence of inflammatory action in the tissues of the appendix or cæcum, and when no indurated mass can be discovered by palpation in either, after careful exploration the incision may be closed without any probability of serious consequences.

If, however, on the contrary, appendicitis is verified, with or without the recognition of a solid body within its canal, it would be proper to ligate or suture the cæcal attachment, and excise the appendix vermiformis as a security against further inflammatory developments in its structure. Thus, all liability to the graver results of perforation would be most effectually obviated, and thus surgery of a destructive order would eventually prove to be conservative in preventing other grave consequences. The diagnosis of appendicular disorders cannot be guaranteed without an exploratory operation, as the statements of those most familiar with this class of cases show most conclusively, and it cannot augment materially the risk to life, while it insures a radical cure when disease exists.

An incision may be made outside of the right rectus muscle. The extension of the opening upward along the linea semilunaris would be indicated in case a suppurating track should be discovered, as was noted in my case of perforation of the appendix.[1] This was shut off from the general peritoneal cavity by adhesions, so that it left the iliac fossa and reached the diaphragm on the right side, burrowing behind the liver in the form of a cloaca, which could not have been explored properly by an incision in the linea alba, owing to the adhesions existing there between the intestines and the abdominal wall.

In a recent laparotomy for volvulus of the ileum, near its cæcal connection, such difficulty was encountered in the exploration of the seat of disease through an incision in the median line from the umbilicus to the pubes, that it was found necessary, in order to effect my object, to extend my incision upwards to a point midway between the umbilicus and ensiform cartilage. The walls of the intestine involved in the twist were agglutinated and the canal entirely occluded, and there was also disintegration of the ileum on each side of the obstruction. The cæcal segment was ligated, and the other was cut beyond the gangrenous line and stitched into the median incision, as is done in the process for artificial anus upon closing the abdomen.

If the site of the trouble could have been known in advance, as is presumed to be the case in appendicitis, it would certainly have required a shorter incision in the linea semilunaris than was found necessary in the linea alba in the case just referred to. I avail myself therefore of the opportunity to modify my criticism in the paper read at Chicago, upon the opening of the abdomen at the outer border of the rectus muscle, and fully realize its advantages in operating for appendicular extravasation.

The great advantage of the several steps consists in adapting the extent of the operative procedures to the nature of the case. If there be a doubt in the diagnosis of appendicitis it is solved by a transverse incision in the iliac region, and if nothing be revealed requiring further surgical interference, the opening may be closed by suturing the peritoneum with catgut in continuous form, while the fascia, muscles and skin are brought together by interrupted sutures of iron-dyed silk. There will not occur much strain upon the suture in this line of union, and the operation should not be carried further except when the evidence of disease in the adjacent structures demands a larger field of observation. Incisions along the linea semilunaris upward or downward, with the turning aside of the corresponding flaps, will afford ample scope for operation in cases of circumscribed abscesses in general peritonitis, resulting from the perforation of the appendix vermiformis.

It has been my object in this paper to direct attention to the early development of inflammation in the structure of the appendix, as its progress and termination in perforation have proved serious in most cases; and the intractability of the consequences produced by extravasation of its contents, as manifested by suppuration and peritonitis, is generally recognized by surgeons.

I am not prepared to assert that a differential diagnosis of appendicitis can be assured prior to perforation, but a reasonable presumption in favor of the seat of the disorder being in the structure of the appendix, may be reached by a careful examination of the local signs and the general symptoms. In view of the strong probability of the existence of appendicular trouble it is asserted that an exploratory operation is justifiable in

[1] Medical and Surgical Reporter, April 30, 1887.

advance of any indications of perforation, thus choosing the lesser evil of an unnecessary incision, rather than risk the greater in the calamatous results of extravasation of the contents of the appendix into the peritoneal cavity, accompanied by shock and followed by septicæmia.

The difficulties which the surgeon must encounter from delay in resorting to an operation until perforation assures him of its necessity, should warrant him in forestalling the danger by an exploratory incision so soon as he becomes impressed with probability of appendicular inflammation; and if this belief is realized, the exploratory operation is made a radical operation.

THE POST-NASAL SYRINGE A CAUSE OF MIDDLE EAR DISEASE; WITH AN ILLUSTRATIVE CASE.

BY WILLIAM M. MASTIN, M.D.,

MOBILE, ALABAMA.

Notwithstanding the fact that a warning note has been sounded from more than one source concerning the disastrous consequences to the middle ear that may result from flooding the naso-pharyngeal space with fluids, medicated or otherwise, the numerous journal reports, together with the recommendations in many of the recent special treatises, particularly foreign publications, on diseases of the rhino-pharynx, attest to the recklessly indiscriminate employment of methods of this character for cleansing and medicating the nasal and pharyngeal cavities.

The first to call attention to the occurrence of otitis media following the use of the nasal douche was Dr. D. B. St. John Roosa, of New York, who, in 1869, reported[1] an example of acute suppurative inflammation of the middle ear with ulceration of the membrana tympani arising in this manner; and then later, with an amplification of this case, he published[2] a table of sixteen instances of middle ear disease produced by the douche, occurring in the practice of different surgeons. At the same time he gave admonitory advice against the rough or careless use of the posterior nares syringe in acute or subacute catarrh, instancing an example of acute aural catarrh with drum perforation occasioned thereby; and since then these statements have been confirmed by numerous observers, who have noticed and recorded similar facts regarding both the douche and the syringe.

It is true, however, that not a few rhinologists believe these views to be erroneous, asserting that the douche, besides being a most useful appliance in the treatment of rhino-pharyngeal diseases, when properly and carefully handled is entirely devoid of ill effects, and this opinion they support by a weighty array of statistics; but, it must be conceded that there is already on record a sufficient number of such mishaps in the hands of prudent and skilful surgeons to demonstrate that this and like measures are not so positively innocuous as is claimed by their advocates.

The subjoined case is an additional illustration of this fact, and is of especial interest since it shows that the post-nasal syringe, although fully recognized as not altogether harmless—but, at the same time, considered quite safe in comparison with the douche—is an instrument which must be employed with the utmost caution and circumspection.

Sallie ——, a little girl of 12 years of age, who had been under my professional care at intervals during a period of two years for a chronic rhino-pharyngitis associated with middle ear catarrh, reapplied in January, 1887, on account of a slight return of the nasal and aural symptoms. She now received, as formerly, the usual treatment by sprays, powders, etc., each application being preceded, of course, by inflation of the Eustachian tubes, and the use of an alkaline cleansing solution applied by means of the ordinary post-nasal syringe.

The syringe had been employed in this manner a great many times without any unpleasant effects whatever, although no especial precaution had been observed in its application. At 11 A.M., on January 20, I proceeded to cleanse the nasal spaces in the same way, using for this purpose Dobell's solution with "Listerine." At the instant the fluid was discharged from the syringe she complained of a sharp, cutting pain in the left ear, which caused her to cry out, and clasp with her hand the painful ear. The fluid was injected slowly and gently, not forcibly, but I noticed that there was a decided spasmodic action on the part of the pharyngo-palatal muscles which tightly grasped the extremity of the syringe. The intensity of the pain subsided in a few moments, but a dull, heavy ache remained until after the use of a hot water douche; and examination revealed an injected and congested drum

[1] *Archives Ophthalmology and Otology*, Vol. 1, No. 1.

[2] "Practical Treatise on Diseases of the Ear," fifth edition, p. 296, 1881.

membrane, but no bulging. She remained in my consulting room until all pain had disappeared, when she was sent home with instructions to summon me upon the slightest recurrence of suffering. This was not obeyed, however, and I learned that the pain returned in about an hour after leaving my office. This, at first, was throbbing in character, accompanied by a full, heavy sensation in the face and head on the affected side, and becoming exquisitely intense as evening approached. Her mother employed opium, both internally and locally, hot fomentations, etc., but with very little relief until after daylight when the pain suddenly began to lessen and was quite gone within a half hour. Coincident with the subsidence of the pain she noticed a sanguineous discharge, which saturated a plug of cotton-wool, placed in the meatus to retain the anodyne applications, and trickled down upon the pillow. I saw her at midday (January 21), when a small quantity of half-dried bloody fluid was found in the external tube, and a rent in the posterior and inferior quadrant of the membrana tympani plainly visible.

Active measures were immediately taken, and very fortunately the case went on to complete recovery: the perforation healed rapidly, hearing soon rose to the normal, and within the space of a few weeks there was nothing to indicate the occurrence of the accident.

The injurious action of the douche is rightly attributed by Dr. Roosa to the direct passage of a flood of liquid into the tympanic space; but he evidently considers the syringe as harmful only through its irritative or abrasive action to the pharyngeal mucous membrane around the tubal openings—the inflammation thus originating extending along the Eustachian tube to the tympanum —as is shown by the following paragraph, referring to its use: "In cases of acute inflammation of the pharynx attended with considerable swelling, it should be used with care, or it will abrade and irritate the mucous membrane of the pharyngeal wall. This abrasion may then lead to an extension of the inflammation along the tube to the tympanic cavity. *In chronic cases I have never seen or heard of any harm being done by the posterior nares syringe.*"[3] The italics are mine.

In the present instance the acute aural catarrh was undoubtedly the immediate result of the entrance of liquid into the cavity of the tympanum, since the sudden sharp pain at the moment of injecting the fluid can be explained in no other rational way.

It is very clear, therefore, that the nasopharyngeal syringe may be productive of harm in both acute and chronic cases, and by two methods: first, the direct entrance of liquid into the Eustachian tube and tympanum; and, second, an irritation or abrasion of the mucous membrane around the faucial extremity of the tube, produced by the syringe nozzle, leading to an inflammation which quickly advances along the canal to the sensitive and repellent tympanic cavity.

Whilst I do not wish to be understood as absolutely condemning the posterior nares syringe as an instrument which should be discarded from the armamentarium of aural and pharyngeal appliances, I am desirous of emphasizing the necessity of exercising the greatest care and gentleness in its employment, and, also, of restricting its use to a much fewer number of cases. When it is used, it should never be emptied of its contents with a jerk by suddenly and forcibly driving the piston home, but the liquid should be gently and slowly discharged in a continuous stream; and should a spasmodic grasping of the syringe point take place, the instrument should be either withdrawn entirely, or allowed to remain quietly in position until the pharynx becomes tolerant of its presence, or, perhaps, local anæsthesia of the pharynx may be resorted to with advantage.

Leaving out of consideration the practical lesson furnished by this case, I am opposed on general anatomical and physiological grounds to flooding the nasal and pharyngeal spaces with any considerable volume of liquid; and, furthermore, I am convinced that the spray is the only sensible and effective method by which these cavities may be safely cleansed or medicated.

[3] "Treatise on Diseases of the Ear," p. 291.

—At a recent meeting of the Agricultural Society of Paris, M. Torney, professor of arboriculture, put in a note on sewage water. He thinks that the culture of the Jerusalem artichoke would suit very much better than that of any other ordinary vegetable for the rapid absorption of matter in suspension in sewage water. The Jerusalem artichoke attains a height of eight to ten feet, which does not admit of the wind getting to substances on the surface of the soil, and so prevents to some extent the propagation of epidemics.

LOCAL APPLICATION OF BALSAM OF COPAIBA IN INFANTILE LEUCORRHŒA.

BY J. B. JOHNSON, M.D.,
WASHINGTON, D. C.

Leucorrhœa is common to women of all ages. That of young female life is most commonly limited to the vulva; and it is the exception for the inflammation which excites the discharge to extend far into the vagina. When the inflammation does reach into the vagina, the disease is usually quite severe, and is attended with a copious discharge and swelling of the vulva, accompanied by heat, pain and distressing itching. When the labia are separated with the fingers, the mucous membrane, not only of the labia but of the mouth of the vagina, will be seen to be intensely red, tumefied and covered with an unhealthy looking muco-purulent discharge, varying in color from a white to a yellow or greenish hue, and resembling in external appearance the discharge of gonorrhœa. This resemblance of the leucorrhœal discharge to that of the gonorrhœal, sometimes gives rise, in the minds of parents, to the supposition that their child has been criminally dealt with; but such an impression will be easily dispelled not only by the history of the case, but by the absence of marks of injury from criminal violence, which when present usually cause rupture of the hymen, bruising and swelling of the labia and surrounding parts, attended with a more or less copious trickling of healthy blood from the wounded tissues of the external genital organs.

The most common exciting cause of the disease I have found to be an herpetic or eczematous eruption about the vulva, which, in consequence of the intense pruritis excited by the presence of these eruptions, forces the child to scratch and rub her parts with violence, creating not only much irritation to the vulva but also to the vagina. This repeated and excessive rubbing of the external organs of generation by the child with her hands, is often the first sign which leads the mother to investigate the cause of the child's uneasiness; and upon examination the mother generally finds the labia red and swollen, and covered with scaly incrustations of the dried discharge, and upon separating the lips of the vulva she will see purulent or muco-purulent matter issuing from the vagina, and the presence of the disease is thus ordinarily detected and confirmed. Scrofulous girls are most susceptible to this disease. It sometimes occurs during or follows an attack of scarlet fever, and does occasionally arise from cold and from infection. During its progress it is much aggravated or prolonged by the existence of dentition, worms or constipation. Its predisposing cause resides in an innate liability to inflammation of the mucous membranes, which is now and then seen to be a part of the constitutions of some individuals. As there are persons born to great liability to inflammation of the serous membranes, so there are those who come into the world with a high susceptibility to inflammations of the mucous membranes; and it is this diathesis that explains why a child may have infantile leucorrhœa from "*cold*," caused by insufficient clothing of the lower extremities, or from sitting on the damp ground, or upon cold surfaces of door steps or stones.

The discharge is highly contagious, and a healthy girl child may be infected by sleeping with one who has the discharge; and a child so affected should not be allowed to sleep in the same bed with another child or even with its own parents, for instances have been known of mothers being infected by sleeping with their little daughters while suffering with the disease, which often maintains a tedious course of several weeks or more. The cloths and towels used to dry the parts of girls thus affected, should never be used to wipe the face, or indeed any part of the body; for if the slightest portion of the discharge should get into the eyes, acute and dangerous ophthalmia is almost certain to be excited. In order to guard against such accidents, the mother should always be informed of the activity of the contagious character of the discharge of infantile leucorrhœa.

Treatment.—This disease will persist in being very tedious in its course, if absolute cleanliness and partial rest are not firmly insisted upon during the application of the remedial measures which may be adopted for its cure. The mother should be instructed to wash well the external genital organs of the child at least four times a day; and this cleansing should be performed in the morning as soon as the child gets up, and at noon and evening, and just before the child goes to bed. As a wash for this purpose, I usually order the following, to be used tepid, in cold weather:

℞ Pulv. borax.....ʒij
Water.....f ʒv
Glycerine.....f ʒj
Carbolic acid.....gr.x.

M. S.—Shake well and use four times a day.

After the parts have been well washed, I order finely powdered oxide of zinc, or oleate of zinc, to be freely sprinkled, or powdered between and over the lips of the vulva. Ordinarily, I find this simple treatment to cure the case; but unfortunately, the disease often extends from the vulva far into the vagina, giving rise to severe vaginitis; and when I meet with a case in this condition, I am in the habit of relying upon the local application of balsam of copaiba for its cure. After each washing, I direct three or four drops of the copaiba to be dropped into the mouth of the vagina, and allowed to remain there, and to diffuse itself over the various parts of the vulva. The dropping of the copaiba into the vagina should be conducted while the child is lying upon its back, with its hips elevated by a pillow, and the labia majora separated as widely as possible; and the child should be allowed to remain in this position for five or ten minutes after the application of the copaiba. Should the pure copaiba excite too much irritation, it may be mollified by mixing with equal portions of cocoa-butter or carbolized vaseline, and put into the vagina with a camel's-hair-brush as far as this is practicable. While the local treatment is in progress, I prescribe the following as a tonic and alterative:

℞ Sulph. magnesia.....ʒj
Caraway water.....fʒviij
Iodide of potassium.....ʒij
Fowler's solution.....fʒj

M. S.—Shake well and give one teaspoonful to a tablespoonful, three times a day, according to the age of the child.

When severe pain in micturition attends the discharge, it will be found to be caused by fine inflamed points of mucous membrane situated about the orifice of the urethra, and these projecting points are most quickly destroyed by the application, once in every two or three days, of nitrate of silver. During treatment, the child should not be allowed to go to school, and should be restricted in its usual exercise. Indeed, the less exercise the child is allowed to take, the sooner will a cure be attained; and this fact should be impressed upon the mind of the mother; and she should also be informed that the treatment should be continued in a less rigid manner for several weeks after the discharge has disappeared; for if this rule is not observed, the discharge will most certainly return after its apparent disappearance. The diet should be generous and nutritous; while those articles of food apt to irritate the alimentary canal should be strictly forbidden.

DEATH AFTER ADMINISTRATION OF CHLORAL IN LABOR; FIRM CONTRACTION OF THE UTERUS.

BY JACOB R. LUDLOW, M. D.,
EASTON, PA.

A woman, about eighteen years of age, primiparous, came under my observation some time ago, suffering from puerperal eclampsia at full term. She had been bled from both arms, had taken chloroform inhalations, and, during the night, two rectal injections of chloral hydrate—at least eighty grains in the two injections.

When I saw her the next morning, she was pallid, entirely unconscious, with a small, feeble pulse—about 120, with shallow, frequent, noiseless respirations, and extreme contraction of the pupils. There was very great œdematous swelling of the lower extremities. Finding the os dilatable, I produced podalic version, and in about thirty minutes delivered a large male child, still-born, flaccid, with the appearance of having been dead some hours. I operated slowly, regardless of the life of the child, fearing to encounter atony of the uterus with immediate fatal hemorrhage; but the uterus contracted firmly and the secundines came away without trouble. After the delivery she did not manifest any noticeable change. She seemed in good condition except for the extreme anæsthesia.

I saw her by request the next morning, about twenty-four hours after her delivery. Her condition was unchanged, still pale, with pulse and respiration as when I left her the previous day, perfect unconsciousness and loss of voluntary motion, the conjunctival reflex and deglutition abolished. The uterine globe was firm and distinct, and there had been absolutely no leakage. The œdema of the legs was considerably diminished. She was ordered whiskey per rectum, but died the following night, about thirty-six hours after delivery.

Perhaps the most noticeable thing in this case is the lethal anæsthesia, with abrogation of deglutition, voluntary motion and consciousness, with cardiac and respiratory centres almost paralyzed, and this persisting continuously for more than thirty-six hours; while yet the innervation of the uterus was unaffected and the womb retained its tonicity to the last.

I think it is fair to infer from it that chloroform and chloral hydrate do not in any degree impair the power of the centres which give energy to the uterine contractions.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, April 11, 1888.

The President, J. Solis-Cohen, M.D., in the Chair.

Dr. J. M. Barton read

A Report, and Exhibited the Specimens, of Some Cases of Abdominal Surgery.

By invitation of the Board of Directors of the Philadelphia County Medical Society, Dr. Barton submitted some specimens from cases of abdominal surgery and presented the notes of them:

"*Case I.—Abscess of liver. Free incision and drainage; recovery.*—George B., aged thirty-eight years, was admitted to the medical wards of the Jefferson Medical College Hospital, July 29, under the care of my colleague Dr. Neff. The patient was suffering with an immense abscess of the liver, extending the area of the percussion dulness to below the umbilicus and to the left of it. At the request of Dr. Neff, I removed by aspiration more than a quart of "brick-dust" colored pus, with such relief that the patient was able to return to his home in the interior of the State. The abscess cavity rapidly refilled, and he returned to the hospital, when we decided to operate by the method of Dr. Ransohoff, of Cincinnati: making an incision through the abdominal wall, five inches in length, at the outer edge of the right rectus muscle, permitting it to gape, fastening the edges of the wound by sutures to the liver, and when firm adhesions had taken place, opening the liver by the galvanic knife. When adhesions were found to have formed, and I attempted to divide the tissues of the liver with the galvanic knife it did not act well; at first, while white-hot it would cut readily, but the resulting very free bleeding quickly short-circuited the current and the knife became instantly cold. After repeated trials it still proved so unsatisfactory that an ordinary scalpel was substituted, with which the pus cavity was reached. An attempt to check the bleeding from the margins of the incision, by the cautery knife, was also unsuccessful, and it was only by filling the wound with a number of rubber catheters, which happened to be at hand, that the hemorrhage was controlled.

The abscess cavity was washed out daily with various antiseptics; it gradually closed, and the patient was discharged cured. When Dr. Neff saw him the following December, his weight was one hundred and fifty-six pounds, his pulse beat eighty to the minute, and he had no evidence of hepatic disease."

Case II.—This was a case of epithelioma of the œsophagus, in which gastrostomy was done and death resulted. The patient was a man 42 years old.

Case III.—This was a case in which an unmarried woman, 36 years old, had a large uterine fibroid. On making an exploratory incision it was found that universal adhesions would prevent the removal of the uterus or of the ovaries. The patient recovered.

Though previous to the operation she almost invariably bled for ten days at each menstrual epoch and at least twice between the menstrual flows, immediately after the operation the excessive bleeding ceased, and for nearly two years she regularly menstruated but three or four days; she did not lose more than one-fourth of the quantity each day that she had prior to the operation and there was no bleeding whatever between the menstrual periods. Her pains have ceased since the operation, her general health has greatly improved, and she looks much younger. Ever since the operation she has been, and is now, following her occupation as a school-teacher. Nothing was done at the operation to account for this improvement, which is great enough to have been considered quite a success if the ovaries had been removed. The tumor is gradually increasing in size, and is now beginning to interfere with respiration.

"The next case is one of so much interest that I am anxious to have it on record, though the principal part of the operative treatment was not performed by myself. The laparotomy was performed by my colleague, Dr. F. H. Gross, when I was a member of the staff of the German Hospital, during his term of service; the herniotomy by myself during my term, though we were both present, and took active part in both operations. I am indebted to Dr. Gross for permission to report this case:

"*Case IV.—Strangulated hernia. Operation; loss of nine inches of intestine; subsequent laparotomy; several feet of bowel found obstructed by inflammatory deposits; bowel above the obstruction joined to bowel below the obstruction; recovery.*—Frank F., aged 18 years, was admitted to the German Hospital on the evening of March 3, 1884, with a strangulated right inguinal hernia of eighteen hours' duration. On opening the sac of the hernia nine inches of the bowel was found to be in a sloughing condition. The ring was nicked, the healthy ends of the bowel

made to protrude, and the gangrenous portion incised. We proposed, on the next day, to freshen the edges of the healthy bowel and bring them together. By the following morning the patient had developed an intense peritonitis with a temperature of 104°, and the operation was postponed. After a week of severe illness he recovered, the sloughing bowel having separated in the meantime.

Some weeks later, as he was slowly emaciating, and the discharges looked as though the artificial anus was high up the bowel, operative interference was decided upon. The wound was enlarged, directly upward, at first but slightly, but ultimately to the extent of several inches, for the purpose of joining the divided ends of the bowel.

In the neighborhood of the artificial anus from two to three feet of intestine were found, strongly matted together by inflammatory deposits; small projecting loops of a few inches in length were found free with both ends terminating in the mass. The lower end of the bowel, from which the slough had separated, could not readily be distinguished from any of the other loops; and it soon appeared that it would be useless to join it to the bowel which formed the artificial anus, as it was completely obstructed at many points. As the colon was free, and a few inches of the ileum, at the suggestion of Dr. Weed, then one of the resident physicians, it was decided to join the bowel forming the artificial anus to the colon. For this purpose a small opening was made in the cæcum, and one blade of Dupuytren's enterotome introduced, the other being carried into the bowel forming the artificial anus, and the two blades clamped together. A temporary ligature was placed around both intestines while the toilette of the peritoneum was made; they were then fastened in position, and the wound, about six inches in length, closed.

The patient did well after the operation, though it was found necessary to reapply the enterotome twice before a satisfactory opening was obtained, three times in all. The fæcal fistula rapidly contracted, and when I last saw him he was able to wear a pad over it for a week without removal; his bowels acted naturally, he was free from pain, gaining flesh, and was working as elevator boy at the hospital.

I heard afterward that another surgeon had attempted, though unsuccessfully, to close the fistula."

Case V.—This was a case in which a married woman, fifty-four years old, had an ovarian cyst which ruptured. Ovariotomy was performed, and the patient died on the fourth day.

Case VI.—This was a case in which a man, thirty-one years old, had an encysted pelvic abscess. The abdominal and visceral peritoneum were stitched together, the abscess emptied and drained, and the patient recovered.

Case VII.—In this case double ovariotomy was performed on a married woman, twenty-eight years old, for multilocular cysts, weighing about forty pounds. The patient recovered.

Case VIII.—In this case a large fibroma of the uterus was removed from a married woman, thirty-two years old. The uterus and ovaries were removed by abdominal section, and the patient died on the fourth day.

"*Case IX.—Stricture of the ileo-cæcal valve, chronic obstruction of the bowels. Laparotomy; digital dilatation of the stricture; recovery.*—Mrs. Ann H., aged thirty-seven years, a patient of Dr. D. S. Jones of Plymouth, Pennsylvania, was admitted to the Jefferson Medical College Hospital in May, 1887. She had been in good health until the birth of a child in May, 1886. Since then she had had repeated and increasing attacks of obstruction of the bowels; during which there were entire loss of appetite, obstinate constipation, constant vomiting, great abdominal pain, and tenesmus, similar, she stated, to labor pains. Lately there had appeared at these times a tumor about the size of the adult fist in the lower part of the abdomen; these attacks occurred about once a month, and as they lasted three weeks she had but a short interval of comfort between them. When free from the attack, she stated that the tumor returned to the right iliac fossa, where she thought she could distinguish it by palpation and by its tenderness on pressure. I was unable, at this time, however, to recognize any unusual mass in this situation.

I kept her under observation until an attack should occur. On May 21 an attack began, and her sufferings fully verified her statements. The tumor appeared between the umbilicus and the pubes, it was about the size, and very nearly the shape, of the adult kidney.

On May 2, 1887, in the presence of Professors Gross, Parvin, Brinton, and several other physicians, I made a median incision about four inches in length and exposed the mass; it proved to be an intussusception of the ileum into the colon with a thickened and contracted ileo-cæcal valve forming the apex of the intussusception. There were

slight adhesions between the contiguous layers of peritoneum covering the bowel, which were readily broken up, and the intussusception reduced. On examining the ileo-cæcal valve by a finger invaginating a fold of the colon, it was found to be hard and contracted. A longitudinal incision was made in the colon about one inch in length, and three from the valve, through which I passed my finger and found the valve contracted to about the size of a crow's quill (one-fifth of an inch). It was slightly thickened, quite hard, white in color, and did not bleed during the examination or subsequent manipulations. It was considered by all present to be a case of cicatricial stenosis due to some previous inflammatory action, and certainly not malignant. It was dilated, with considerable difficulty, by the introduction of the little finger, and the index finger was then carried through its entire length.

The wound in the bowel was closed by a continuous silk suture, including only the mucous membrane; the peritoneal coats were brought in apposition by a continuous silk Lembert suture.

All the operative procedures upon the bowel were performed outside of the abdominal cavity, the abdominal wound being kept closed by sponges. The portion of bowel outside was thoroughly washed and returned, the abdominal wound was closed in the usual manner.

There was some vomiting after the operation; the patient was kept slightly under the influence of morphine for a few days, and on a milk and broth diet. The bowels opened naturally on the eighth day, the stitches were removed on the fifth and sixth days; the temperature never rose above 100°. She returned to her home entirely free from all her previous symptoms, and remained free for several months."

[For her subsequent history, see Case XIII, page 600].

"*Case X.—Obstruction of the pylorus. Digital dilatation by Loreta's method; death from exhaustion.*—George H., German, aged fifty-eight years; blacksmith. His health had always been good until the last year. At the time he came under my care he had the typical symptoms of complete pyloric obstruction, with a well-marked tumor at the usual situation. It was not very large nor hard, had no marked outlines, and presented the characters of pyloric thickening more than those of a malignant growth. The microscopical examination of the matters vomited gave no evidence of malignancy, and no vomiting of blood had occurred. He was greatly emaciated, and so feeble that at first I refused any operative interference; the operation had, however, been explained to him, and its performance promised before he came under my care, and he insisted so strongly on having a chance for prolonging his life that I consented.

The operation was performed at Jefferson Medical College Hospital May 22, 1887, in the presence and with the assistance of Professor Brinton, Dr. Wirgman, and quite a number of others.

As the patient's condition warranted no further interference than mere dilatation of the pyloric orifices, and as the usual incision to the right of the median line would have exposed the stomach nearer to the pyloric orifice (as shown by the position of the tumor) than I desired, I made the incision directly in the median line, and about three inches in length, beginning an inch and a half below the ensiform cartilage.

The stomach was readily exposed three inches from the pylorus. The examination of its exterior threw no new light on the character of the growth, though the stomach at this point was found to be slightly adherent to the structures beneath. An incision, a little over one inch in length and three inches from the pyloric orifice, was made in the stomach, parallel to and directly beneath the abdominal incision; the coats of the stomach were much thickened. Complete stenosis of the pyloric orifice was found when the finger was introduced, but this was readily dilated with the little finger. While the tumor was supported outside the abdominal walls with the left hand, the orifice was then further dilated with the index finger.

The thickening and infiltration of the walls of the stomach at the point of incision prevented the use of the Lembert suture; their softened condition evidently required the suture to pass through all the coats. As the abdominal wound was directly over that in the stomach, the latter was closed and brought in contact with the abdominal wound, so that the visceral and parietal peritoneum might adhere, and if any of the contents of the stomach should escape or any pus form, they might readily drain outside and not into the general peritoneal cavity. Fine silk with two needles were used, these were carried from within outward through all the coats of the stomach, one needle through each lip, then crossed and one brought through each lip of the abdominal wound; a few were carried direct without crossing. These sutures were tied and the abdomen closed.

Nothing was given by the stomach for the first twenty-four hours, the rectal nourishment upon which he had relied previous to the operation being continued. No vomiting occurred during the four days that he lived. On the second day milk and hot water were given in small doses at regular intervals, and as they were well borne they were increased in quantity and frequency. Notwithstanding the fact that he took over a quart of milk per day, besides rectal nourishment, he sank and died exhausted on the fourth day after the operation. There had been no elevation of temperature.

At the autopsy the stomach was found firmly fastened to the abdominal wall; there was no evidence of any peritonitis. In the interior of the stomach it was difficult to find the point at which the incision had been made, the sutures being completely buried in the folds of the mucous membrane. The pyloric thickening was inflammatory in character, and not due to any malignant growth.

There was complete obstruction previous to the operation, there was none after, and had the patient been subjected to operative interference earlier there is no reason why his life might not have been greatly prolonged."

"*Case XI.—Ovarian tumor. Removal; recovery.*—Miss A., aged thirty-eight years, had noticed a pain less abdominal enlargement for a few months. On examination I found a small ovarian cyst, lying in the median line and rising slightly above the umbilicus. On May 23, 1887, with the assistance of Drs. Da Costa, Edward Graham, Sweet and Fisher it was removed. The incision was about three inches in length, the tumor was non-adherent. It was tapped, drained, and removed in the usual manner; its pedicle was tied with silk and dropped.

The peritoneum was brought together with chromicized catgut, the interrupted silk suture being used for the other tissues. The patient made an uninterrupted recovery, her temperature never rising above 99°. The tumor weighed about fifteen pounds."

"*Case XII.—Two penetrating stab wounds, one puncturing the liver and one the transverse colon. Laparotomy; recovery.*—Michael H., aged twenty-five years, was admitted to the Jefferson Medical College Hospital at 3 P.M., of September 9, 1887. About three hours previously he had been stabbed twice with a small and pointed amputating knife, during a quarrel in a house of ill-fame.

There were two wounds, both penetrating the abdominal cavity, both at the outer edge of the right rectus muscle and both running diagonally toward the median line, and penetrating the peritoneum at that point. The upper was one and a quarter inches long and was just below the edge of the ribs; it terminated in the left lobe of the liver, and from it there was free venous bleeding.

The lower wound was three-quarters of an inch long; it was three inches below the upper and just above the level of the umbilicus. After hurried antiseptic preparations, I opened the abdomen in the median line from the ensiform cartilage to the umbilicus, and found an opening about five-eighths of an inch in length in the transverse colon parallel to its length and near its mesenteric attachment; this was closed by the continuous silk Lembert suture. The suture failed to control a small artery in this wound, but a separate stitch carried under it and tied secured it.

The wound in the liver was small, it had ceased oozing, and as its lips were in fair contact no suture was used. The abdomen was cleansed, the wound closed and dressed in the usual manner.

The following morning his temperature was 101° and in the evening 100°; after that, though it kept quite low, varying from 98½° to 99°, he had a sharp attack of peritonitis, lasting three days, during which time there was constant regurgitation of bloody fluid. The abdomen was painful and greatly distended with gas, requiring the constant use of the long rectal tube to relieve him. The stitches were removed on the fourth and fifth days, and the abdomen supported by adhesive plaster. He was discharged cured on September 29, having been in the hospital twenty days."

"*Case XIII.—Epithelioma of the ileo-cæcal valve. Resection of three inches of intestine; recovery.*—Mrs. H., aged thirty-eight years, the same patient whose ileo-cæcal valve was dilated seven months before (see Case IX, page 598), came complaining of a return of her former symptoms; her sufferings were slight, but were evidently of the same character as before the first operation.

November 1, 1887, with the assistance of Drs. Allis, Kendig, Stillwell, and the resident staff, I again opened the abdomen. A straight incision parallel with the median line was made; it was three inches in length terminating at a point one inch outside the middle of Poupart's ligament. The incision was made at this point as the nearest to the portion of bowel I wished to attack, because I feared adhesions might have formed after the last operation, rendering it inaccessible from any distant incision; and, further, if it became necessary to form an artificial anus, it would be a convenient point.

I had decided that if it should prove to be a recontraction of the stricture, to make a longitudinal incision about two inches in length carried through the ileum, ileo-cæcal valve, and cæcum, bringing the two ends of the wound together and sewing it up transversely; this would best be made on what would be the under surface of the bowel when the patient stands erect. I tried this on the cadaver and found it practicable, and that it increased the circumference of the bowel, at that point, about two inches. The head of the colon was readily found, there was no return of the intussusception, no no adhesions had formed, though in reducing the intestine at the first operation there had been slight bleeding at a number of points at which adhesions were torn. The scar of the original intestinal incision was scarcely perceptible. At the ileo-cæcal valve, however, there was now a decided tumor, and it was now evidently epitheliomatous. An incision was carried into the mass and verified the diagnosis. The entire valve had become an irregular mass of epitheliomatous tissue varying in thickness from a half an inch to an inch, entirely obstructing the gut except an aperture in the centre, about one-third of an inch in diameter. The circumference of the valve was less thickened by the disease than the centre. The abdominal wound was now closed by sponges, leaving the diseased parts outside; three inches of the bowel, including the disease, were removed; no clamps were used, the bowels being held in the hands of an assistant; a few vessels were tied.

As the mortality is very high when the separated ends of the bowel, in these operations, are sewed together and returned, I had decided if it became necessary to excise, to establish a temporary artificial anus and begin at once the proceedings for its cure. With this end in view, immediately after the removal of the diseased bowel and the ligation of the bleeding vessels, one blade of Dupuytren's enterotome was introduced into each portion of bowel, viz., one into the ileum and one into the colon, the two blades were brought together and the screw run down firmly. A strong ligature was placed on the ends of the bowel, including the enterotome, to prevent the escape of fæces during the subsequent manipulations. The bowel was washed, placed in position at the lower angle of the wound and fastened there with a continuous silk suture. The abdominal wound was closed, covered with cheese cloth saturated with mercurial solution, and this in turn with patent lint soaked in sweet oil. This is the best method that I have found to protect abdominal wounds close to an artificial anus. The heavy ligature around the ends of the bowel was now removed. A ring of cotton soaked in oil was placed around the artificial anus, the outer extremity of the enterotome supported by oakum, and a wide bandage pinned over it. Morphine was used hypodermically during the first forty-eight hours and then discontinued; vomiting occurred during the first two days and then ceased. Some fæces appeared on the evening of the operation, and full quantities two days later. On the eighth day the enterotome was found loose, and was removed; its removal was preceded by a passage of fæces from the natural outlet. The stitches were removed on the third and fourth days, and the wound supported by adhesive plaster. After the removal of the clamp the patient was permitted to rise, and all restrictions removed from her diet.

The bowels acted naturally for a few times, when all the fæces came again from the artificial anus. The clamp was again applied on the 17th, and came away on the 28th. Its removal was again followed by a few natural passages. As these ceased in a few days the clamp was applied for the third time with a precisely similar result. As this had proved ineffectual, the method of Mr. Banks, of Liverpool, was used. A strong ligature was fastened to the middle of a heavy piece of rubber gas tubing about six inches in length; one end of the tube was passed into one bowel, the other end of the tube into the other bowel, the middle of the tube pressing against the spur. The position of the bowel in this case was such that the rubber tube was retained with difficulty. After trying it for ten days without success, I substituted the apparatus which I here show, consisting of two pieces of very heavy rubber gas tubing joined together like the letter T. The upper part of the T is about one and a half inches long, and presses directly against the spur; the other tube is three inches long, and merely serves to keep the first in position. The large base is circular, is three inches in diameter, and serves as a pad to prevent the escape of fæces from the artificial anus. The three pieces of rubber are joined firmly by a strong wire running from the first to the last piece, and twisted tight. This method proved at once satisfactory, and a large proportion of the fæces began at once to pass by the natural outlet, and continued to do so. The patient is now in the hospital, but I shall make no attempt to close the fistula until it is seen if the bowels will continue to act naturally.

During this prolonged treatment, fearing that the colon, from disuse, might contract, I directed that she should be given an injection of a quart of water daily, and I was surprised to hear that when a pint had been given it appeared at the artificial anus. By continuing these injections the capacity of the colon was rapidly increased, and when last tried it held three pints; of course, when the bowels began to act naturally this was discontinued."

"*Case XIV.—Chronic obstruction of bowels by encephaloid tumor. Exploratory laparotomy; artificial anus established; recovery from the operation; death fourteen days later from obstructive peritonitis arising from tumor.*—Francis O. B., aged thirty-eight years, Irish, carpet porter, a patient of Dr. James Robinson, with whom I saw him January 18, 1888. He was in perfect health until June, 1887, when he began to have slight cramps, once or twice daily, and occasionally at night, in the left iliac fossa. He continued working until December 24, 1887, and has been confined to bed since. His attacks had not increased greatly in severity, but he was getting much weaker. He had lost fifty pounds in weight; he vomited once or twice a week; it was not stercoraceous. He suffered greatly with tenesmus, which produced from ten to fifteen passages during the night, each being a small, hard, white mass about the size of a cherry.

The left iliac fossa was slightly tender. The abdomen was distended with gas. The pulse was 104, and the temperature normal. His pain was uninfluenced by food. He had never passed blood by the bowel. The rectum was found empty and unobstructed.

Later I removed him to Jefferson Medical College Hospital, by which time his pain was nearly constant, and he was unable to sleep without large doses of morphine. Some days after admission his temperature increased to 103°; there was increased abdominal tenderness and other evidences of a slight attack of peritonitis, which disappeared in forty-eight hours. On the 28th he passed wind by the penis, and again on the 30th.

On January 30, 1888, with the assistance of Drs. Allis, Nancrede, Robinson, and the house staff, I opened the abdomen. A median incision about four inches in length was made, and a lobulated tumor the size of an orange was found in the angle between the bladder and the spine. The sigmoid flexure of the colon was tightly adherent to and partly buried in the tumor. The cæcum was carried toward the median line, and was also adherent to the tumor. The lower end of the ileum was closely adherent, and its calibre nearly obliterated.

The colon was contracted and collapsed; all the bowels above the point of obstruction in the ileum were greatly distended.

As nothing could be done with the growth, a fold of the ileum a few inches above the point of obstruction was brought out of the wound and fastened in its lower angle by a few silk sutures; a rubber drain was introtuced, as a glass one failed to reach the desired point, and the abdomen closed. The drain was removed about twelve hours later, as I feared to have it remain in such close proximity to the artificial anus. Twenty-four hours after the operation the fold of bowel in the wound was opened, and the artificial anus established.

On the second day the patient was placed upon his usual food, stimulants, etc. The stitches were removed on the fourth and fifth days; the wound healed promptly. It was successfully kept from contamination by the fæcal discharges, by the method described in a case reported above.

At the operation a fold of bowel was brought entirely out of the wound; this was adopted as a modification of the method of entirely cutting off the bowel, closing the lower end with sutures, and using the upper to form the artificial anus.

The method here adopted has the advantage of rapidity, less danger of contaminating the cavity with fæcal matter, as the opening of the bowel may be postponed until firm adhesions have formed. It permits any gases or other material that may be imprisoned in the lower bowel to escape, and quite as effectually prevents any material passing the artificial anus into the lower bowel.

The patient was relieved of his pain, the vomiting ceased, and he slept well; had a fair appetite, and improved in appearance. All fæcal discharges, and they were very copious, came from the artificial anus, and none by the natural outlet after the first twenty-four hours.

On the thirteenth day there was a slight elevation of temperature, and all fæcal discharges suddenly ceased; injections of warm water carried some distance above the opening by a soft catheter were without effect; by evening vomiting and other symptoms of acute obstruction occurred, and he died twenty-four hours later, or fourteen days after the operation.

The *post-mortem* examination was made on the same day. The abdominal wound was solidly healed; the bowel, at the artificial anus, was firmly attached to the abdom-

inal opening. The abdominal cavity contained quite a quantity of opaque serum; the opacity was greatest near the tumor, and on pressing the tumor, thick, purulent-looking fluid exuded from it. This was probably the orgin of the fatal peritonitis. The bowels were but slightly congested, and only at one point, about twelve inches above the artificial anus, were adherent. The bowel at this point was sharply flexed upon itself, and adherent for about three inches, causing complete obstruction. This adhesion was readily broken down by the finger, and it would probably have yielded to an active saline.

The condition of the bowels, as found at the time of the operation, was verified; the tumor was broken down, and had ulcerated into the sigmoid flexure; a large number of secondary nodules were scattered through the liver. The microscopical examination was made by Dr. Longstreth; the tumor and the nodules from the liver were reported by him to be encephaloid.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, April 23, 1888.

The President, Laurence Johnson, M.D., in the Chair.

After the passage of resolutions concerning the death of Dr. C. R. Agnew, the scientific paper of the evening was read by Dr. W. C. Jarvis, entitled,

The Indications for the Surgical Treatment of the Deflected Nasal Septum, with an Analysis of One Hundred Cases.

There were, the author said, definite symptoms and pathological complications easily recognized and explained as being more or less directly associated with deflected nasal septum, and which afforded excellent guides in the treatment of this complaint. Such guides, however, had not been pointed out in any single paper, and it was to supply this want that he addressed the Society.

His cases included only those which had been treated in private practice and of which he had kept the detailed history. In forty-two of the cases the deflection of the septum was to the right, and in forty-seven to the left, while in eleven it was bilateral. Seventy-eight were purely cartilaginous, seventeen were osseo-cartilaginous, five were osseous deflections.

The principal indication for surgical interference was nasal stenosis, which was present in eighty-one of the cases. Among the most important complications which should be recognized from the start as special indications for an operation were hypertrophies of the turbinated bones. These were present in twenty-four per cent. of the cases of deflection to the right, in eight of which an operation was required to remove the redundant tissue; and in twenty per cent. of the deflections to the left, requiring operative interference in four cases. Posterior hypertrophies were present in fourteen per cent. of the cases. Slight redundancies of the turbinated tissue which were present in all cases of deflected septum were not considered. The next most common complication was trouble with the ear, it being present in twenty-nine cases. In some the operation was undertaken for the relief of this alone. The bulk of these were in physicians who recognized the necessity for perfect ear ventilation.

The eye was complicated in a marked manner in eleven cases. Well marked catarrhal headache was present in fifteen cases. Other complications were hay fever, polypi, bronchitis, etc. Hypertrophic rhinitis was present in ninety-four cases; atrophic rhinitis in six.

The stenosis which was so common was in some cases complete, while in others it was incomplete, or alternated from complete to partial. Snoring was common, and while this might occur without stenosis, it was frequently caused by stenosis, and might in persons of delicate health be of serious import. Nasal stenosis was capable of producing pharyngitis, laryngitis and bronchitis. Dr. Jarvis thought it might, under favoring conditions, induce phthisis. It is sometimes caused by a dam-like accumulation of the fluids in the nose, and made an operation necessary to open up the nasal gutters. Some patients had been operated upon unnecessarily, an acute congestion of the turbinated tissues having been mistaken as a symptom of septal deflection. The diagnosis could be made by the lapse of time, use of cocaine and the rhinometer.

Conditions in which an operation was not indicated were named as follows: 1. Extra nasal deflections. 2. Cases in which the septum was deflected, but so far forward as not to interfere with the rise and fall of the turbinated tissue. 3. Deflected non-obstructive septa. 4. Non-obstructive deviations in the nostril exhibiting a pale or normal hue of the pituitary membrane. 5. Slight localized non-obstructive bending of the vomer placed above the level of the nasal floor and occupying the more spacious portion of the nostril. 6. Cases of considerable deflection,

non-obstructive, presenting a smooth regular surface and gentle undulation.

In twenty-four per cent. of the cases the snare alone was employed, in twenty-nine per cent. he used the septum scissors, in eleven, the fracture forceps; in six, the surgical drill, and in thirty the electrical drill.

Dr. Bucklin thought we could not form an opinion as to the amount of space required in the nostril for breathing purposes by a comparison with the size of the lumen of the tube used in laryngeal intubation. There should be room for free play of the mucous membrane covering the turbinated bones, which varied with the temperature in different individuals. He thought nasal stenosis required especial attention as it so frequently led to catarrhal deafness. In the class of cases under discussion there resulted changes in the connective tissue in the nose, attended by the secretion of tenacious mucus. This would not cease immediately after removal of the deflection of the septum, overcoming the stenosis, and for that reason patients had often regarded the treatment as a failure in not overcoming the chief symptom from which they had suffered. He had a patient whose commencing phthisical symptoms disappeared at once after overcoming the stenosis.

Dr. Clarence Rice regarded surgical interference performed gently and by a careful operator as less heroic treatment than the use of swabs and douches so commonly resorted to a few years ago, and still much employed by many who condemned surgical interference.

Dr. Phillips thought the indications for treatment were to enable the person to breathe freely through the nostrils. After an operation the treatment of the wound was of special importance to avoid adhesion of opposing surfaces.

Dr. Tansley had in a number of instances had occasion to treat patients for a suppurative otitis which had been excited by operations upon the nose in patients whose auditory difficulty had not been of an active kind.

Dr. Beverley Robinson favored the use of caustics and the cautery.

—Dr. S. G. Dixon suggests in the *Therapeutic Gazette*, April, 1888, that the usual model of suppositories for the rectum be so changed as to make the present base a short cone. When the suppository is introduced by this short cone beyond the internal sphincter, the contraction of this muscle upon the longer cone will force the entire suppository further up the bowel.

Hospital Notes.

THE TREATMENT OF PUERPERAL SEPTICÆMIA AT THE PHILADELPHIA LYING-IN-CHARITY—WITH REMARKS.

CHARLES P. NOBLE, M.D.,
SENIOR ASSISTANT PHYSICIAN.

The treatment is based upon the principle that puerperal seticæmia is caused by the entrance into the system of an infectious material through lesions in the genital passages. This infectious material is believed to be certain micro-organisms, which produce their effects either directly by their action on the fluids and tissues of the body, or indirectly through certain products of their activity, called ptomaines, or both.

The prime object of local treatment in puerperal septicæmia is to render and maintain the utero-vaginal canal in an aseptic condition. It must be recognized, however, that when once the germs are within the tissues or vessels of the puerpera, they are beyond the influence of local medication. Hence the result to be hoped from local antisepsis is that it will limit the dose of poison to that which has been absorbed before treatment was instituted. The tissues and white blood cells must be left to battle with those germs which are already within the tissues, assisted by constitutional medication. Therefore the results from local treatment are most brilliant in cases of putrid infection, where the fever is due rather to the absorption of the products of decomposition of the lochia, or of fragments of retained placenta or membranes, than to the action of germs on the tissues of the patient.

Other objects to be gained by local treatment are to favor the healing of wounds, and promote the comfort of the patient.

Neither septic abscesses of the pelvic cellular tissue nor pyæmic abscesses have developed in the Charity's cases (within three years), nor has phlegmasia dolens been observed. In two cases gonorrhœal salpingitis has developed *in puerperio*. In one—an outpatient—peritonitis succeeded, laparotomy was done by Dr. Longaker, the diseased tube removed, and irrigation practiced. The patient was *in extremis* before the operation, and died shortly afterward. In one case an old pyo-salpinx induced purulent peritonitis and death, without operation. These cases are mentioned to show the variety of conditions usually classed as "puerperal fever."

Where a diagnosis of puerperal sepsis is made, local irrigation is instituted at once, irrespective of the odor of the lochia. Where the temperature does not exceed 102° F., vaginal irrigation alone is practiced. This is for the reason that infection takes place in the majority of cases through lesions of the vagina or vulva, and only exceptionally from within the uterus. Corrosive sublimate solution (1–2000 to 1–4000) is used. The irrigations are repeated at intervals of three or four hours by the nurse. Where the fever does not subside in from six to eight hours, or increases, the uterus is washed out by the physician himself. This necessitates a digital examination, when bits of placenta or membrane, if present, are removed by the finger. The dull curette has been used to some extent, both for diagnosis and the removal of foreign material from the uterine cavity, and is regarded with favor. But no mere instrument can give the information derived through the sentient examining finger; nor will any inflict so little traumatism in the removal of foreign bodies. The uterine cavity is examined only after vaginal irrigation, lest having previously escaped, it be infected by the septic vaginal discharges carried on the finger. The modified Bozeman canula is used. A hundred grain iodoform pencil is left in the uterus. This slowly disintegrates and is present in the discharges for two or three days. After this thorough disinfection, the fever, especially if due to putrid absorptions usually disappears. Otherwise vaginal irrigation is continued as before; and should new chills occur, or high temperature continue (above 103° or 104° F.), the uterus is again washed out and the iodoform pencil left in as before. The woman need not be disturbed during the manipulations. The vaginal irrigation is discharged in a bed-pan, then the canula is introduced within the uterus along the finger, as a guide. All air is previously expelled and the stream allowed to run during the introduction. Irrigation is continued until the stream returns clear—from one to three pints are necessary. After removing the canula the uterus is grasped and made to expel all fluid, and the perineum slightly retracted to insure its discharge from the vagina. Dr. Wilson sometimes irrigates through a speculum. No case of serious mercurial absorption has occurred. Salivation was induced in one case. No case of iodoform poisoning has been seen. Not infrequently after the intra-uterine douche, and quite commonly after the removal of more or less putrid material from the uterus, a chill and rise of temperature results, which soon subsides. This is partly due to nervous shock and partly to the temporarily increased absorption of poisonous material, caused by abrasions produced during the manipulations of the finger, curette or irrigat or.

In those unfortunate cases in which fever continues in spite of treatment, it becomes a question, after several days, whether irrigation is of further value. Fetor of the lochia is a constant indication, but it is not apt to be present after the removal of foreign matter and thorough utero-vaginal disinfection. In the presence of marked parametritis, without special indications to the contrary, the vagina alone should be douched.

On one case diphtheritic patches occurred on the fourchette. They were treated by the application of pure carbolic acid followed by iodoform.

Turpentine stupes, and at times poultices, are used in cases of metritis or peritonitis, with tenderness on pressure, and tympany.

Constitutional treatment, while considered in the majority of cases of secondary importance to local measures, is by no means neglected. Nor is it forgotten that in the cases in which marked invasion of the tissues and vessels by germs has taken place (before local antisepsis could cut off the supply), it is the only means of favoring a successful issue. The indications are to support the strength, combat hyperpyrexia, and meet special complications and symptoms. It is a problem of "the survival of the fittest" between the host and the invading germs.

Proper alimentation is of the highest importance, especially in protracted cases. Milk, given in quantities that can be assimilated, is largely depended upon. In irritable stomach lime water or whiskey is added. Beef tea, nutritious broths, and the various nitrogenous prepared foods are used as adjuvants, or where milk disagrees. Quinine in divided doses, not exceeding fifteen grains daily, is believed to conserve the strength. Whiskey is given as indicated. Most cases at all protracted, require it early, and can take it in large amounts. The first sound of the heart is the most reliable criterion by which to be guided in its administration. Brandy is at times substituted, and champagne is used where troublesome and otherwise uncontrollable nausea is present. The administration of spirits is considered of great value in combating septic fever.

Hyperpyrexia (approaching 104° F.), unless transient, is met by antipyrin (grs. xv to xx) repeated every hour or second hour, until the temperature falls below 102° F. The pulse is always watched during its

administration, and stimulants given if necessary. In two cases, which subsequently recovered, collapse occurred after the administration of two fifteen grain doses of antipyrin at intervals of an hour, the temperature falling to 97° F. Quinine in fractional doses is substituted when the temperature is below 102° F., being used principally for its tonic effect. The cold coil has been used in a few cases.

Opium is largely relied upon to allay restlessness, induce sleep, and relieve pain. Pain is very seldom complained of; tenderness on pressure is usually its greatest manifestation.

In the few cases in which peritonitis has been present, turpentine by the mouth and by enema has been used to relieve flatus. The question of opium *versus* saline purgatives is under consideration, but it is by no means considered advisible to prevent an occasional movement of the bowels.

For weak heart, while digitalis is used, more is expected from alcohol and alimentation. Ergot is believed to be of use in preventing septic absorption, not only by favoring an empty and contracted uterus when used *post-partum*, but also, perhaps, by its action on the muscular tissue of the utero-vaginal canal and absorbents, in the presence of septic material.

Other special complications and symptoms when present, are treated on general therapeutic principles.

Special Correspondence.

THE DAY BEFORE THE ASSOCIATION MEETS.

Cincinnati, May 7, 1888.

The day before the opening of the meeting of the American Medical Association is usually characterized by the gathering of a large portion of the members. Some of them come early so as to avoid the crowding and inconveniences of the first day, and some to meet their friends and talk over matters in which they feel especial concern, before the time for action arrives. In this respect the present occasion does not differ from its predecessors. The hotel corridors are thronged with active and earnest-looking men. Everywhere clusters of chairs are drawn up and men lean over toward each other as they talk and listen; and it is clear that the business of the Association is being discussed, and perhaps, arranged by those who make up the groups.

At this moment two questions are being actively discussed. The first is, who shall be the next President of the Association? The second is, where shall the next meeting be held? In regard to the presidency, three names are being canvassed: those of Dr. Moore, of Rochester, of Dr. Dawson, of Cincinnati, and of Dr. Matthews, of Louisville. Each name is supported by warm friends.

Dr. Moore and Dr. Dawson are urged for the office on the ground of their age and standing in the profession, and the fact that they are men whom the Association may appropriately honor with this distinction. The name of Dr. Matthews is being advocated chiefly on the ground that he is young, energetic, a good parliamentarian, and likely to be able to maintain order and discipline in the business meetings of the Association. Some recent experiences have convinced a number of the members of the Association that the body needs for the Presidency a man who adds to a high professional standing, familiarity with parliamentary rules and customs, and a quick and firm judgment. How far this opinion may go in the present canvass, it is now impossible to say; but there can be no doubt that it has much in its favor. The outlook now seems to be favorable to the election of Dr. Moore or Dr. Dawson.

At the meeting of the

American Association of Medical Editors,

held this evening, a permanent organization was effected by the adoption of a few articles of constitution. There was a large number of editors present, and an animated discussion took place in regard to the effect, upon medical journalism and the profession, of so-called "trade-journals." The general opinion was that they are of disadvantage to the members of the profession, as well as injurious to regular medical journals. This view was opposed by a gentleman—not a member of the Editors' Association—who was invited to speak on the subject. One of the editors expressed the opinion that there is no use in discussing this question, except as the discussion may lead to better work by the editors and publishers of medical journals; since the only practicable way to compete with the inducements offered by the manufacturing houses which issue journals of their own, is to offer the profession better journals at a reasonable price.

Among the men who are already here, there are many whom it would be a pleasure to name; conspicuous among them are Dr Garnett, of Washington, the President fo

this year; Dr. N. S. Davis, of Chicago; Dr. Garcelon, of Maine, and Dr. Henry H. Smith, of Philadelphia. These are the principle points which were impressed upon me during the day before the meeting of the Association.

On the first day of the meeting, May 8, a large number of delegates and members gathered in the Music Hall, and the meeting was formally called to order by Dr. Dawson, and opened with prayer by Rev. R. A. Gibson. After which, an

Address of Welcome

was delivered by Hon. Amor Smith, the Mayor of Cincinnati. In this address the mayor extended to the members of the Association a hearty welcome to the city. The address was excellent and sensibly brief, and contained amusing allusion to the time, twenty-five years ago, when the then mayor of Cincinnati thought it worth while to issue an order to the police, that for the time they should not be too strict with exhilarated midnight strollers, lest they should by mistake offer an affront to some rejoicing and belated member of the American Medical Association, which was then, as now, the guest of the city.

This order, Mayor Smith said, he would not now issue, lest he should seem to forget that since twenty-five years ago there were women who had entered the portals of the practice of medicine, and even of the American Medical Association, but he assured the members of the Association that everything in his power would be done to make their visit to Cincinnati both pleasant and enjoyable.

Dr. C. G. Comegys followed, on behalf of the Medical Profession of Cincinnati, in another address of welcome. In this, he gave an interesting sketch of the history of that part of the Ohio Valley in which Cincinnati is situated. He portrayed the settlement of this region, its vicissitudes of Indian wars and final deliverance from danger, and the development of its material and intellectual welfare.

Dr. Garnett's Presidential Address followed, and proved to be an able argument in favor of elevating the standard of medical education in this country, favoring a compulsory four years' graded course, a State examination for a license to practice, and cancelling the charters of schools which failed to show a class of at least fifty students for any period of five consecutive years. The address was received with marked manifestions of approval, and made an obvious impression upon the audience.

After some miscellaneous business had been transacted, the general meeting adjourned for the day.

In the afternoon the various sections met in the numerous and convenient rooms of the Music Hall, being well attended in spite of very changeable and threatening weather.

The reception of the Association by the medical profession of Cincinnati is most hearty, and the arrangements made for its accommodation, both scientific and social, are admirable. The members of the Association seem to be generally animated by a spirit of concord and fraternity.

The place of meeting next year will probably be either Philadelphia or Baltimore—most likely the former.

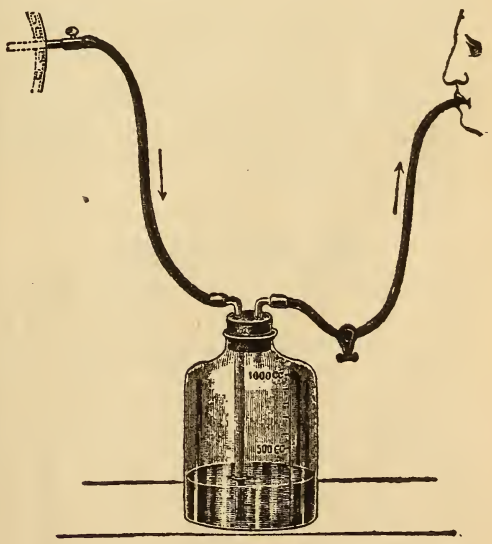
Yours truly. J. C. B.

Periscope.

Apparatus for Removal of Pleuritic Effusion.

In the *Berliner klinische Wochenschrift*, March 26, 1888, Prof. Fürbringer, of Berlin, describes an ingenious and simple apparatus for the aspiration of serous effusions in the cavity of the pleura.

This apparatus, of which we give an illustration, is composed of a receiving-bottle



of about one quart capacity, with a rubber stopper, through which pass the ends of two glass tubes, bent at a right angle, and fitting hermetically. One of these tubes goes nearly to the bottom of the vessel; the other passes only through the stopper. The former is connected with a rubber tube, fitting over a canula three or four millimeters in

diameter, and supplied with a stop-cock; the latter is connected with another rubber tube supplied with a compression-stop. In using the apparatus, the end of the second tube is placed in the mouth of the operator and about three fluid ounces of a warm one to two per cent. solution of boric acid is sucked into the bottle through the other tube. The canula is then thrust with the aid of a trochar into the pleural cavity, the trochar withdrawn, the stop-cock closed, and the tube attached. The operator now sucks a little upon his tube and closes it; then the stop-cock in the canula is opened and the fluid begins to flow into the bottle. As soon as the effusion reaches the fluid in the bottle, the compression of the operator's tube is removed and the effusion will continue to pass into the vessels so long as there is any pressure upon it within the chest. When it ceases to flow spontaneously, its flow may be solicited by suction upon the operator's tube. In this way about a quart of fluid can be removed from the chest without any risk to the patient or inconvenience to the operator. If the quantity to be removed at one sitting is more than a quart, the canula can be closed, the bottle disconnected and emptied, new antiseptic fluid poured into it, the patient's tube re-connected to the canula and the subsequent steps of the preceding procedure repeated. The method described provides for the slow evacuation of a pleuritic effusion in the most gentle and satisfactory way. It has been used by Fürbringer in more than fifty cases without accident or inconvenience, and certainly deserves to be brought to the attention of American physicians.

Hydrastis Canadensis.

In a clinical and pharmaceutical study of the root by Givopiszew (*Thèse*, St. Petersburg, *Bulletin général de Thérap.*, Feb. 29, 1888), the writer presents the following results, which, so he states, are "based upon a large number of clinical observations and experiments upon animals:" 1. The aqueous extract, even in large quantities, did not produce toxic effects in warm-blooded animals. 2. It always caused a diminution of blood pressure without a previous augmentation. 3. It always induced contraction of the uterus and its appendages. Under the influence of an aqueous extract of hydrastis the most intense contractions took place in cases of advanced pregnancy, or soon after delivery; the contractions were weakest in the virgin uterus. 4. Large quantities of the extract may induce premature delivery in the second period of pregnancy. As clinical results, the author concludes: 1. Hydrastis is an excellent agent to combat uterine hemorrhages due to inflammation or false positions of the organ, as also against hemorrhages following the catamenial period, and in the case of too abundant menstrual losses. 2. Uterine contractions produced by hydrastis are less intense than those from ergot of rye. 3. Its use produces no untoward effect upon the organism. Even when taken for a prolonged period it causes no gastro-intestinal troubles, and often ameliorates dyspepsias which have previously existed.—*Amer. Journal of Pharmacy*, April, 1888.

Prevention of Syphilis.

The Paris correspondent of the *Medical Press and Circular*, February 15, 1888, states that M. Fournier has presented to the Academy of Medicine the report of the Committee appointed to inquire into the best means of preventing the spread of syphilis. The following are the principle articles: 1. The Academy calls the attention of the authorities to the development to which prostitution on the streets has grown, and demands that energetic means be taken to repress it. 2. The legion of wine-shops only assist clandestine prostitution and should be suppressed. 3. A strong and active surveillance should be exercised in the neighborhood of the colleges, where temptation is rife. 4. A girl proved to be contaminated should be sent to a special sanitary hospital, from which she should not be discharged without being furnished with a medical certificate; at the same time the rules of the hospital should have in nowise the stringent character of the present St. Lazare. 5. The registered women should be visited regularly once a week and once a month by a medical inspector. 6. Instead of increasing the number of beds in certain hospitals in which venereal diseases are treated, new special hospitals should be created outside the walls of Paris, to which free dispensaries should be attached. 7. Every student of three years' standing should have free access to all these institutions, and before presenting his thesis he must produce a certificate justifying a three months' *stage* in one of these services.

—An engine-fitter residing near Bolton, England, recently died from the effects of drinking an infusion of one ounce of colchicum seeds and a drachm each of iodide of potassium, slippery-elm, and guaiacum, the ingredients having been sold to him by a local herbalist.

Epithelioma of Penis and Scrotum; Complete Removal of External Genitals; No Recurrence at the end of Six Years.

F. A. Southam, assistant surgeon to the Manchester Royal Infirmary, reports the following case: John T., 55 years old, was admitted into the hospital in June, 1881, suffering from well-marked epitheliomatous ulceration of the penis. About twelve months previously the right testis had been removed for what had been regarded as "strumous disease," otherwise he had always enjoyed good health, and there was no history of syphilis. Amputation of the penis was performed, and the patient left the hospital at the end of the month, with the wound not quite healed. Between two and three months subsequently he returned with a recurrence of the ulceration, which presented all the appearances of epithelioma, in the stump of the penis and scrotum; the latter was somewhat extensively involved, a sinus leading down to the left testis, which from implication in the disease had become adherent to the scrotal tissues; the inguinal glands, though slightly enlarged and tender, appeared to be free from any secondary deposits.

In August, 1881, the stump of the penis, the remaining testis, and almost the whole of the scrotum were removed by two elliptical incisions carried wide of the disease, just sufficient integument being left on either side to meet in the middle line and cover over the extensive wound. The urethra and corpus spongiosum, which had been divided far back, were dissected out, turned downwards, and attached by sutures to the skin at the lower angle of the wound.

The patient made a good recovery, and left the hospital at the end of September. The wound had almost healed, and he was able to pass his urine very freely through the perineal opening. He attended as an outpatient during the next few months, and was then lost sight of. Nothing more was seen or heard of him until September, 1887, when, after an interval of six years since the operation, he came to the hospital to show that he was still alive and well. He stated that he had enjoyed good health since last seen, and had never experienced any difficulty with his urine. The perineal opening, which had not shown any tendency to contract, was large enough to admit a No. 10 catheter, and the urine was passed in a very good stream. He was quite free from any evidence of recurrence of the disease, either in the cicatrix or lymphatic glands in the groin.

The author remarks that the successful result in this case must be attributed to the fact that at the second operation the parts were removed wide of the disease, and that the lymphatic glands had not become the seat of any secondary deposits. Inasmuch as six years have now elapsed since its performance, the cure may be regarded as permanent and complete.—*Medical Chronicle*, March, 1888.

Case of Myxœdema.

At the meeting of the Medico-Chirurgical Society of Sheffield, January 19, Mr. W. Makeig Jones presented a case of myxœdema in a married woman, 50 years old, which had been gradually coming on for the last four or five years. About two years ago slowness of speech and general swelling of the skin was noticed. The symptoms were: Great anæmia, with limited rosy patches on both cheeks, centre of forehead and lips. Firm elastic swelling, not pitting on pressure, of the whole cutaneous surface, and also of the mucous membrane of mouth and throat. Commencing atrophy of both optic discs. Pupils sensitive to light. Characteristic thickening of skin over anterior triangle of neck. The thyroid gland, especially the left lobe, larger than in women of the same age. Systolic basic bruit. Exaggerated patellar reflex. Characteristic spade-like hands. Urine about one pint in twenty four hours; pale, sp. gr. 1014—1020, full of phosphates, but not albuminous (it contained albumin eighteen months before). Temperature in mouth 96°. Pulse 48–60. General lethargy, slowness of speech, and stammering (she could, however, read fluently), slowness of movement, sensation and intellect. Unpleasant taste, but not smell.—*Medical Press and Circular*, February 8, 1888.

Laparotomy for Intestinal Obstruction Due to Gall-Stone.

We learn, says the *Lancet*, Feb. 11, 1888, that Mr. Charles Stonham has recently performed laparotomy in a case of intestinal obstruction, and found a gall-stone firmly impacted in the ileum, about twenty inches above the ileo-cæcal valve. The stone was removed by a longitudinal incision about one inch in length, and the wound closed with a double row of fine silk sutures. There was recent peritonitis of the gut above the stone, but none below. The patient, a woman, 66 years old, died fifteen hours later. Symptoms of obstruction had lasted forty-eight hours.

Experience in the Use of Cocaine.

Dr. Edmunds says that on applying cocaine subcutaneously for the production of local anæsthesia, it is not advisable to use a stronger solution than five per cent. In his earlier cases, in which this strength was used, constitutional symptoms were never seen; but when, owing to the anæsthesia in one case not being sufficient, he used stronger solutions, there occasionally occurred one or more of the following symptoms: pulse becoming very rapid, weak, and almost imperceptible; sense of faintness and feeling of distress in the region of the heart, blueness of lips, cold perspirations, restlessness, amounting almost to convulsive movements, and dilated pupils. Happily these symptoms never lasted very long; but as nothing of this sort was seen with a five per cent. solution, it seems better not to go beyond that strength.

Cocaine will entirely prevent the pain of the injection of tincture of iodine into the tunica vaginalis for the cure of hydrocele. In two cases a solution of five grains of cocaine in fifty minims of water, was injected through the canula after the fluid had been drawn off. When, after the lapse of five minutes, tincture of iodine was injected, there was no pain or feeling of faintness, nor were there any constitutional symptoms from the cocaine. The iodine and the iodide of potassium in the tincture of iodine react with the cocaine chemically, but these changes do not prevent the cure of the hydrocele. It is true that the injection of a saturated solution of carbolic acid in glycerine into a hydrocele sac does not cause pain; but this treatment is apt to fail.—*Lancet*, January 7, 1888.

Pulmonary Endarteritis.

At a meeting of the Pathological Society of London, February 21, 1888, Dr. G. F. Crooke showed specimens from a case of pulmonary endarteritis. The patient had complained of shortness of breath, pains in the left side and back, pain and fulness in the abdomen, and swelling of the legs. At the necropsy there was found stenosis of the mitral valve, probably congenital, hypertrophy of the left auricle, great hypertrophy of the right ventricle, and dilatation of the pulmonary artery. The smaller branches of the latter vessel showed great thickening of the intima, which was roughened and nodose, and was undergoing fatty changes. The smallest twigs showed marked obliterative endarteritis, and contained small adherent thrombi. There was no systemic atheroma. —*Lancet*, February 25, 1888.

Transudation and the Influence of the Blood-pressure upon the Behavior of Transudates.

Prof. H. Senator, of Berlin, concludes an article in *Virchow's Archiv*, Bd. cxi, Heft 2, Feb. 1888, with the following statements:

All transudates, without exception, contain albumin in solution, but in a smaller quantity than the blood-plasma. The quantity of albumin is smallest in normal transudates and in œdema of the skin. The albumins of the transudate are the same as those of the blood-plasma, namely, serum albumin, serum globulin and fibrinogen. Concerning their ratio to one another and to the quantity present in blood-plasma, little is known. The quantity of saline constituents in the transudate is pretty nearly the same as that in the blood-plasma, but varies slightly. Not rarely it surpasses that of the blood-plasma in the same person. All transudates contain such other non-colloid bodies as are in solution in the blood, bodies which never pass out in pure glandular secretions, such as biliary coloring matter and hæmoglobin. Substances not preformed in the blood are not found in any transudate, unless the latter has become decomposed. Tissues which produce transudates lack the specific powers of gland cells. Filtration experiments performed outside the living body are not decisive with regard to the influence of blood-pressure upon transudation. Rise in venous pressure effects increase of the quantity of the transudate and of its contained albumins, while the amount of its saline constituents is not materially changed. Rise in arterial pressure (*i. e.*, active hyperæmia) appears in the same manner to increase transudation. Nothing definite is known concerning the quantity of albumin in transudates occurring in simple arterial hyperæmia. Section of the sympathetic nerve seems to increase the quantity of albumin in the area of transudation. The quantity of saline constituents in the transudate is not materially changed in arterial hyperæmia.

—A plan for an enlargement of the Pennsylvania Hospital has been proposed, which will more than double the capacity of the hospital, and at the same time leave sufficient grounds around the building to make them attractive for convalescents. It is said that at the meeting next month a plan will be considered for a building fronting on Spruce street, with suitable annexes for the accommodation of physician, surgeons and nurses.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium,	**6.00**
Physician's Daily Pocket Record,	**1.25**
Reporter and Pocket Record,	**6.00**
Reporter, Compendium and Pocket Record,	**7.00**

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 7,500 copies.

AN IMPORTANT STEP IN VACCINATION.

In these days of antiseptic surgery, when it is believed that the most serious consequences may follow the introduction into the human system of germs which are constantly present in the air and on the surface of the body, it is a somewhat singular spectacle to see men who are full believers in the germ theory habitually doing a thing which according to this theory must be exceedingly dangerous. We refer to the practice of vaccination as it is ordinarily carried out. In this procedure a portion of the skin is scratched until the corium is reached, and then a portion of vaccine virus is thoroughly rubbed into it with the aid of sufficient moisture. It is the misfortune of physicians and patients that there is no practicable way of securing supplies of vaccine virus which will insure its entire freedom from the germs of erysipelas or some other disease; and, no matter how careful and conscientious the vaccinator may be, he may inoculate his patient with something very different from what he intended.

But there is another source of danger to the patient which does not depend upon the nature of the virus used, and which may have its share in producing the violent inflamed sores and profound constitutional disturbance which too often follows vaccination. This source of danger lies on the skin of the patient, in the shape of dead epithelium, which may have undergone some decomposition from the action of the perspiration, or of morbific organisms which have been deposited in it.

We believe this source of danger in vaccination has not received the attention it deserves, and that it would be profitable for some investigator to try to learn what proportion of bad arms are the consequence of the failure of physicians to render aseptic that portion of the skin of their patients which they select as the place for vaccination.

Meanwhile we would urge upon our readers the desirability of making it an invariable rule to thoroughly cleanse the site of vaccination with water and soap—and perhaps some antiseptic—and brisk rubbing; so that, if a bad arm follows, they may feel that they have not neglected so simple a step, which is suggested by common-sense and made almost imperative by the accepted tenets of general surgery. To vaccinate an unwashed arm ought, we believe, to be regarded as an error in practice.

TREATMENT OF PENETRATING WOUNDS OF THE ABDOMEN.

At a recent meeting of the Société de Chirurgie, of Paris, M. Reclus brought up for discussion the subject of the treatment of penetrating wounds of the abdomen, and more especially of pistol-shot wounds. From a careful study of the subject, and from the result of a number of experiments on dogs, he has come to the conclusion that a considerable proportion of cases in which the intestine is penetrated by a small body will recover spontaneously, and that the statistics of laparotomy do not offer anything better to the surgeon than is shown by his own studies of the result of expectant treatment combined with physical and physiological rest.

This view is diametrically opposed to that which is now current in the surgical world, and especially in this country. So it is interesting to note that it has not been admitted without question even in France. The Paris Society of Surgery has followed the subject up in a discussion which engaged the voices of the best surgeons of that city. The general conclusion was altogether favorable to what is recognized as the "American" idea: that laparotomy should be performed boldly in cases of penetrating wounds of the abdomen, where there is any reason to suspect that the bowel has been penetrated. According to Trélat, the chances are ninety-seven in a hundred that the bowel is penetrated when the abdominal wall is; and the views of Reclus are not borne out by general surgical experience.

It is well known that penetration of the stomach is not so likely to be followed by serious peritonitis; and this fact may be borne in mind in determining the propriety of laparotomy in individual cases; but in general we believe the whole surgical world accepts the view which is called the "American" view, and is not prepared to abandon it upon the ground of such evidence as M. Reclus has brought forward, no matter how fully both he and it are deserving of respect.

CURIOUS BACTERIO-THERAPY.

A few medical men have been carried away by that singular product of latter-day cerebration: "bacterio-therapy;" and a very few have actually attempted to put it into practice and have "set a thief to catch a thief" by administering the bacteria of one morbid condition to counteract the effects of the bacteria of another. This curious idea has not had much following, however, and appears now to have died the death it deserved.

But a communication of M. Frémont to the Société de Biologie of Paris, at its meeting on April 7, 1888, seems to look in the same direction. M. Frémont reports that an examination of the waters of Vichy has disclosed to him the presence of different varieties of micro-organisms in the waters of different springs, and he believes this fact accounts for the different medicinal properties of these waters, which he says are "almost" identical in chemical composition. It is hardly likely that M. Frémont has overlooked the fact that waters almost identical may produce different effects, for this reason alone; and the differences observed at Vichy must in his opinion be of a character which cannot be explained on a chemical basis. If this be the case, his appeal to the bacteria contained in it can be regarded only as an illustration of a sort of belief in bacterio-therapy. This is very curious; but it requires much further elucidation than M. Frémont has given it, before it can be accepted as of great scientific value. It would be interesting to have a full account of the character and numbers of the micro-organisms which he has found in Vichy water, and there ought to be little trouble in controlling his observations so as to determine whether there is something or nothing in his singular announcement.

CARE OF THE INSANE IN PENNSYLVANIA.

So long as insanity is one of the afflictions of the human race, one of the most interesting subjects of medical and humane thought must be how to provide for the helping and treatment of the unfortunate beings who suffer with it. The fifth Annual Report of the State Lunacy Commission of Pennsylvania shows that out of over nineteen thousand insane persons admitted to the five State Hospitals up to last year, more than seven thousand have been cured or improved sufficiently to be restored to their families. This admirable result indicates the great improvements which have been made of late in the care of the insane and in the treatment of mental diseases.

Part of the report referred to discusses the question whether or not State hospitals are better places for the care of the insane than county alms-houses. In regard to this matter the Commission is strongly of the opinion that State hospitals are much preferable to alms-houses. We have already, in the REPORTER, April 14, 1888, expressed our own conviction that this is the case; and are sure that a knowledge of what still occurs in the

alms-houses of such enlightened States as New York and Pennsylvania would convince the most skeptical that they are not places for persons whose care and treatment demand so much skill and patience. We hope the time will soon come when no insane person will be confined in any establishment which is not especially designed for this purpose, and governed by men who have special fitness for such a work.

KUSTER'S OPERATION FOR HERNIA.

In the *Centralblatt für Chirurgie*, March 17, 1888, Prof. Küster calls attention anew to and advocates his method of operation for hernia. This method has been fully described a number of times. It consists in opening the sac in the usual way, restoring the bowel to the abdominal cavity, cutting off the sac, and stitching the edges carefully. After this the hernial opening is stitched, and the rest of the wound is closed by successive rows of continuous catgut suture, so that there is no space left for any accumulation of blood or serum between the cut surfaces. After the skin is sutured, the wound is painted with iodoform-collodion until no blood can come through the coating. After this no further dressing is applied.

Küster maintains that this method accomplishes all the objects of the usual antiseptic method, while it is much simpler than the latter. Its success depends largely upon the care with which the preliminary steps of the operation are carried out, and the strictly aseptic condition of the wound before it is sutured. Küster's opinion of its value is supported by the results he has obtained with it in thirty-three cases, in only two of which death followed the operation, and in neither of which was it attributable to the method.

Such a simple plan of treating the wound in herniotomy has much to recommend it on theoretical grounds, and is worthy of the attention of surgeons in this country, as well as in Europe.

VITA NUOVA.

The *Boston Journal of Health* continues its good work of exposing medical frauds by publishing a detailed description of an analysis of Harriet Hubbard Ayer's nostrum called "Vita Nuova." This is recommended—with abundant testimonials, of course—as a safe and sure cure for the alcohol habit. It is probably nothing but a native Port wine.

Our friends of the religious press may reflect upon this, when they sanction the insertion of advertisements containing the false statement that it is positively free from alcohol; and may ask themselves how they must appear to a profession which is not likely to judge such conduct too leniently when they lay themselves open to the accusation of taking money for promoting the schemes of designing and unprincipled adventurers.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

DISEASES OF THE SKIN: A PRACTICAL TREATISE FOR STUDENTS AND PRACTITIONERS. Second edition, thoroughly revised and enlarged. By James Nevins Hyde, A.M., M.D., Professor of Skin and Venereal Diseases, Rush Medical College, Chicago, etc. Philadelphia: Lea Brothers & Co. Price, cloth $4.50, sheep $5.50.

The author in his preface to the second (present) edition states that the volume has been thoroughly revised, and much new matter added; and this statement is verified by almost every page. In fact, so thoroughly has the revision been made that the result is practically a new work The numerous woodcuts, many of which are new, are, with few exceptions, good, and lend value to the book. The classification followed is that adopted by the American Dermatological Association. In a few respects, however, the author wheels from the regular track, as, for instance, in considering lichen-planus and lichen-ruber distinct diseases; in this he is in accord with Kaposi and Robinson. Dermatitis herpetiformis, erythrasma, myxœdema and other new and recently described affections receive attention. An exception is taken to the name of the first-mentioned, that of Dermatitis "*multiformis*" being considered more appropriate and descriptive. Reference is made also to "Prairie Itch," variously known as "Texas Mange," "Swamp Itch," etc. The author goes to the root of the matter, we think, when he states that his "personal experience has led to the conviction that these terms are loosely applied to a group of cutaneous symptoms of diverse origin;" the cases, as a rule, representing pruritus hiemalis and scabies. The operation of electrolysis for the removal of superfluous hairs is clearly and satisfactorily described. With the suggestion "to operate in succession on contiguous hairs when practicable" our experience is, however, not in accord, as under such circumstances conspicuous scarring almost invariably results. The use of cocaine inunctions or hypodermic injections, for the purpose of rendering the operation less painful, is very properly considered unnecessary and inadvisable. The subject of differential diagnosis is con-

sidered at length, and in the matter of treatment, also, it is fully up to date.

In fact, as already intimated, this second edition of Dr. Hyde's treatise is in reality a new work, and we are pleased to say reflects great credit upon its author. The student or practitioner will find it valuable either as a text-book or as a book of reference. The publisher's part has been equally well done.

Correspondence.

Correction.

Dr. P. F. van Hamel Roos, editor of the *Revue Internationale Scientifique et Populaire des Falsifications des Denrées Alimentaires*, thanks for the communication in your esteemed Journal (April 7, No. 14, p. 451), about his experiences with *nickel salts*. He begs to observe, the orthography of his name, as mentioned in your Journal, is not exact, and kindly requests to alter this in the next number of your Journal.

Amsterdam, April 21, 1888.

Correction.

In the article by Dr. Hiram Corson in the Reporter, May 5, on "Quinine, its Use and Abuse," on page 561, first column, thirteenth line from the bottom, read "ten grains, in doses of one or two grains every hour," instead of "ten grains every hour." The mistake is to be regretted especially because it makes Dr. Corson seem to advocate a practice which he distinctly states is both needless and costly. The firm of chemists referred to as the manufacturers of quinine in 1825, should have been Farr & Kunzi, instead of Farr & Kirnzic.

Notes and Comments.

Congenital Absence of the Vagina with Retention of Menstrual Fluid.

Drs. J. S. and A. S. McMurray, of Frankford, Ind., report a case of this kind in the *American Journal of Obstetrics*, March, 1888. The patient, who was 16 years old, came under their care August 2, 1888, with the following history as given by her mother: She is a twin, her mate having died in infancy. She had a mild attack of scarlatina at six years of age, but no sequelæ were recognized. She was of a cheerful disposition, healthy and vigorous, in mind and body, until about sixteen months prior to the above date, when she experienced the symptoms common to the advent of the menstrual function. But as there was no "show," the attempt was considered abortive. A few weeks subsequently the same symptoms supervened, somewhat aggravated. From this time on, these attacks recurred every four weeks with all the regularity of the well-established menstrual function; each time becoming more painful and lasting a longer time, until about six months before they saw her, when they became continuous and she had lost her health and vigor. During this time, the breasts were well developed, together with all the evidences of maturing womanhood. She was constantly under professional surveillance; her attendants gave her morphine and other anodynes for temporary relief, and emmenagogues without limit, but they availed nothing. Presuming hers to be a case of delayed menstruation, no examination of the genitals was made until this time, when she was taking from *three* to *five* grains of morphine a day, without obtaining even an hour's respite from pain. She grew worse and worse, and finally came under their care. She was then exceedingly emaciated and anemic, and her weight was about seventy-five pounds. Her face had the peculiar pinched look characteristic of long suffering and the morphine habit. Upon making an examination, they found the hypogastric region prominent, and easily outlined a well-defined globular mass, very similar to the pregnant uterus of five or six months. The pubes were well covered with hair, and the labia majora well developed, though upon being separated they revealed no introitus vaginæ, but only a shallow *cul-de-sac*, skirted with carunculæ myrtiformes. The perineum was distended; the anus pushed forward, "pouting," as in the second stage of labor. On introducing the finger into the rectum, a tumor was discovered pressing the perineum, and feeling to the touch like the œdematous scalp of a child's head approaching the vulva. It was thought that the uterus could be detected through the abdominal parietes, closely hugging the tumor above. This, however, was a deception as subsequent developments plainly showed. The ovaries were not discovered. The bladder was pushed upward and forward, and it was with difficulty that a catheter could be introduced.

Bearing in mind the history, linked with the facts present, they diagnosticated a typical case of congenital absence of the vagina, with retained menstrual fluid. She was put on tonic and aseptic treatment for several days, and on August 8 was operated on in order to establish a vaginal canal. The patient was placed in the lithotomy position, and the bladder being emptied through a catheter, a strong steel staff was passed through the urethra and held in position, steadying the vesico-rectal septum, and subsequently serving for a guide to protect that organ and the blad

der. The bottom of the interlabial *cul-de-sac* was raised with a tenaculum, and an elliptical section snipped away with scissors, parallel with the lips, one inch in length by half that width. Now, with two fingers of the right hand in the rectum, an exploratory trocar and canula was carefully passed in the direction of the normal vaginal line. When at a depth of two inches, resistance ceased, and the trocar was withdrawn, followed by a small issue of menstrual fluid, confirming the diagnosis. A long probe was passed through the canula which was then withdrawn, leaving the probe in its track, it serving as a guide to direct the advance of the forefinger of the left hand, with which the vaginal track was opened. Through this, there issued a flood of forty-eight ounces of dark, ropy fluid resembling treacle, so tenacious that it could be drawn out in threads a yard long. When the contents were well evacuated, the finger was again introduced, and the opening extended transversely both right and left until it was enlarged to the normal vaginal capacity. On examining the cavity, its walls were as firm as cartilage. Search was made for the uterus, but it was not recognized. The cavity was then thoroughly washed out with a hot solution of bichloride of mercury. A glass plug, as recommended by Sims, one inch in diameter, and three inches long, was then put into the canal. But it would not go as far as necessary, and on searching for the obstruction a stricture of the cavity was manifest, sufficiently close to prevent the introduction of the plug to its full depth. On closer examination, however, this proved to be the *cervix uteri resuming its natural form*, thus showing the uterus and a small portion of the vagina to have been one continuous cavity. The plug was retained in place by a T-bandage. She was put to bed and soon rallied from the anæsthetic. She at once began to complain of severe pains in the pelvis, which were true "after-pains," such as follow labor. She was given a full anodyne, but these pains persisted and did not disappear for nearly a week. Twice a day, for two weeks, the plug was removed, and the cavity thoroughly washed out with the bichloride solution; then once a day, for three weeks.

In a few days she began to build up, and rapidly convalesced. The glass dilator was worn at least twelve of each twenty-four hours, for three weeks after suspending personal surveillance of the case.

After about the tenth day all opiates were suspended; in fact no demands were present for their use, notwithstanding the liberal administration of morphine daily for over twelve months previous. A troublesome diarrhœa followed, attributable to the withdrawal of the drug, but as digestion improved and the system regained the function of assimilation, no further difficulty of this kind was experienced. Five weeks from the day of the operation, she walked into the authors' office, having come ten miles by rail the same morning. She still wears the plug at night, and will do so for a long time. The canal is as nearly natural as scar tissue, forming over a glass plug, can be, so soon after the operation.

Castration and the Development of the Genital Tract.

Dr. Kehrer, in 1879–80, made a series of experiments to ascertain the effect of castration on the development of the genitals in young animals; the results were published in his *Beiträge zur klinischen und experimentellen Geburtskunde und Gynäkologie*. He castrated rabbits between two and three months of age, and killed them one year later. He found that unilateral castration or spaying caused no arrest of development; on the other hand, when the operation was performed on both sides, the genitals and mammary glands remained stationary, never developing beyond the stage which they had attained when the essential organs were removed. Dr. Kehrer attempted to prove which theory was true—Pflüger's, according to which there existed in the uncastrated female a stimulus to growth through periodical irritation of the ovarian nerves set up by the ripening of follicles which goes on long before puberty; or, on the other hand, the theory that spaying caused a disturbance of the blood supply of the remaining genital organs, through the occlusion of the ovarian arteries. For this purpose he ligatured the ovary and ovarian artery in two series of experiments. He found that neither in unilateral nor in bilateral ligature of the tubes or extremities of the uterine cornua, with separation of the ovarian arteries, was the normal development of the genitals in any way affected. He concluded that the ovarian nerves, or some other and unknown influence in connection with the ovaries, played the most prominent part in stimulating the development of the genital tract.—*British Medical Journal*, March 10, 1888.

For Pityriasis Versicolor.

Ihle recommends the following:

℞ Resorcin.....gr. lxxv–c
Castor-oil.....f℥i¼
Alcohol.....f℥iv¾
Balsam of Peru.....gr. viiss
M. ft. liniment.

Acetophenidine.

M. Gueroguiewsky has employed acetophenidine instead of antipyrin. It is a crystalline gray powder, insipid and inodorous, derived from phenol; it is soluble only in twenty parts of alcohol, and is eliminated by the urine, wherein it can be detected by the red coloration with perchloride of iron. In typhoid fever, tuberculosis, erysipelas and pneumonia, in doses of from two and a half to five grains, he found it to act as an antipyretic in from twenty to forty minutes after injection; the pulse and respiration diminishing in frequency, and sweating being induced. It also relieved pain, but doses of eight or ten grains are required to effect this end, as in migraine, cephalalgia and tabetic pains. It never upset the stomach, nor modified any of the other functions of the body; in this respect it seems to be superior to antipyrin.—*Lancet*, March 24, 1888.

Effects of Moderate Drinking on the Heart and Circulation.

Dr. George Harley sums up the effects upon the heart and circulation which he believes follow the moderate use of alcohol, in the following propositions: 1. Alcohol, when indulged in, even well within the limits of intemperance, has a most prejudicial effect on heart disease. 2. Sudden spurts of muscular exertion act most deleteriously on all forms of organic cardiac affections. 3. Mental excitement is a cause of rupture of atheromatous blood-vessels. 4. A mere extra distension of a stomach by wind may suffice to fatally arrest a diseased heart's action. The knowledge of these facts, he says, has for some years past led him to make it an invariable rule to impress upon all patients laboring under diseases of the circulatory system, who desire to minimize the effects of their complaints and ward off as long as possible the inevitable fatal termination, to pay strict attention to what he calls the following three golden rules: (1) Take exercise, without fatigue; (2) Nutrition, without stimulation; and (3) Amusement, without excitement.—*Lancet*, March 24, 1888.

Death from a Druggist's Blunder.

The N. Y. *Evening Post*, April 11, 1888, says that considerable excitement has been caused at Bellows Falls, Vermont, by the result of the examination of the remainder of the medicine taken by one Wm. Riley, April 5, from the effects of which he died. He called at a drug store for ten grains of quinine, which he mixed with whiskey, and then swallowed two thirds of the mixture. Examination proves that the supposed quinine was morphine. The authorities have not as yet taken any action.

Proposed Plan of Supplying Infants with Pure Milk.

The Paris correspondent of the *N. Y. Medical Journal*, April 7, 1888, says:

The *Société de Médecine pratique*, while recognizing that mother's milk is the best for children, cannot, however, overlook the fact that an immense majority of babies are now-a-days brought up on cows' milk, and, as they are of the poorer classes, who cannot pay enough to secure pure milk, it begs the city government to take the matter in hand, and to construct and maintain model dairies, as is the practice in the towns of Stuttgart and Hamburg. A call is made upon the patriotism of the French Government to adopt this plan of securing pure milk for the babies, whose numbers are being diminished by thousands every year, and the hope is expressed that the city will undertake the important work of supplying pure milk at a low price for all the poor babies of Paris. It is not a bad idea if it could be carried out without making a job of it, as would be the result in some countries if it was a government affair.

Method of Identifying Criminals.

The anthropometrical method of identifying criminals, originating in Paris, has been adopted in the prison at Joliet, Ill. In addition to the photograph of the prisoner, accurate measurements of his height, the length and width of his head, the length of the left middle and little finger, of the foot, the forearm, the ear, the stretch of the arms, description of scars, color of the eyes, and so on, are recorded; and it is thus possible to identify prisoners assuming false names with far greater ease than was before possible. It is asserted, that, in the two years that the system has been in operation in Paris, 826 habitual criminals arrested under assumed names have been identified. Besides the practical utility of the system, it amasses very valuable statistical data contributing towards the natural history of the criminal classes.—*Science*, March 30, 1888.

New Resident Physicians.

Drs. James H. MacMillan, W. T. Sharpless, M. G. Miller and C. W. Sharples, who passed the requisite examination for Resident Physicians of the Philadelphia Hospital, entered upon their duties May 2. There are at present 1,629 patients in the hospital.

Vaccination in China.

Small-pox is epidemic in Hong-Kong, and during the week ending January 28, eighty-eight persons died from this disease. A law has been passed by the Governor and Council making the practice of infant vaccination compulsory in the colony, the Chinese member of the Council stating that his countrymen were strongly in favor of it. A local newspaper sent us by a correspondent enables us to learn something of Chinese thought upon the subject, the article referred to being based upon a pamphlet written by a Chinaman named Chang. The object of vaccination in China, it seems, is to purify the child of the fœtal virus which every child possesses, and which is generated by the passions which gave him birth, and this virus is the attractive cause of small-pox and other ailments. The Chinese anti-vaccinationist evidently accepts this theory, but comments on the absurdity of attempting to let this virus out in two or three pustules. Mr. Chang, however, has a ready reply: The fœtal virus congregates about the Gate of Life and the Three Passages. He does not say where these are, but on either arm, between the shoulder and the elbow, are two depressions, the "eddy of purity and cold," and the "lesser estuary," which two communicate by means of veins directly with the Gate of Life. By introducing vaccine, therefore, in the upper part of the arm, it is conveyed by the flowing of the blood along the vein to its goal. For the reason that "blood must be warm before it can flow," (*vide* Chinese text-books) "cold" food must not be given the patient, or rather, to use our popular expression, food which is credited with being "cooling."—*Lancet*, March 24, 1888.

Masculine Attire for Women.

A petition of a somewhat eccentric nature has just been addressed to the Chamber of Deputies by a young French lady. It is nothing less than a demand on behalf of women generally to be allowed to don male attire. The fair petitioner claims that woman will be better at ease and enjoy more freedom in her motions if dressed as a man. She instances the recent calamities in theatres in support of her statement that the loss of life would not have been so appalling had not a great part of the audience worn petticoats. The custom of the fairer portion of mankind wearing male attire is said to have originated in England. In fact, a female society, existing in England, has boldly raised the standard of revolt. At clubs and meetings its members appear in male costume, which, by the way, they wear with more conviction and pluck than elegance. The statutes of the society call upon its members to lose no opportunity of publicly manifesting their rooted aversion to gowns, skirts and petticoats. "This is the only way," said the president of the society," lately, "we shall succeed in overcoming routine, and ridding ourselves of the ugly, heavy, uncomfortable and costly dress we have been condemned to wear for centuries." To this question, however, there is another side, apart from the comical aspect, and were coquetry not in the van to vindicate its rights, with the majority of French women, who would not fail to stand by it, we might predict to the "young French citizeness" and reformer of dress, that routine itself will constitute the necessary damper.

The Use of Acidified Corrosive Sublimate as an Antiseptic.

Some very interesting experiments of great practical importance have recently been made by E. Laplace (*Deutsche medicinische Wochenschrift*, 1887, No. 40, p. 866-7) in the Hygienic Institute of Berlin, on the antiseptic action of corrosive sublimate when used in acid solution. It has long been known that the efficiency of bichloride of mercury is much reduced when it is brought in contact with albuminous substances, owing to the formation of insoluble compounds; thus when applied to animal tissues, the mercury becomes mordanted, as it were, on the surfaces with which it first comes in contact, the sphere of its activity being thus greatly diminished. Laplace finds that five cubic centimetres of blood serum is sufficient to precipitate the mercury from five cubic centimetres of the bichloride solution (1–1000). The formation of this precipitate of albuminate of mercury can be prevented by adding dilute hydrochloric acid (5–1000) to the bichloride solution (1–1000), whereby the antiseptic power of the latter is greatly increased. Similar results were obtained by the addition of tartaric acid. The solution recommended for use consists of 1 part sublimate, 5 parts tartaric acid, and 1000 parts of distilled water. The bandages, gauze, etc., on the other hand, are soaked for two hours in a stronger solution; namely, sublimate 5 parts, tartaric acid 20 parts, distilled water 1000 parts, after which they are wrung out and dried.—*British Medical Journal*, Jan. 21, 1888.

Mastoid Periostitis from Injury to the Auricle.

Dr. Thomas Barr, surgeon to the Glasgow Ear Hospital, reports, among other traumatic affections of the ear, a case of injury to the auricle, exciting mastoid periostitis. The patient was a boy, who stated that three weeks previously a man caught hold of his ears, lifted him off the ground, and suspended him in this way for a few seconds. The boy alleged that there was no pain at the time. A few days afterwards, however, pain and swelling commenced around the auricle, which was treated by hot fomentations. On admission he was suffering from intense pain over the right mastoid region and side of the head. The pain was so severe, that he had not slept for two nights. The auricle was jutting from the side of the head, and the swelling and the œdema extended from the mastoid region very markedly over the temple, right side of forehead, lower eyelid, and front of ear. The swelling over the forehead pitted deeply under pressure with the tips of the fingers. There was, however, very little redness anywhere. The internal ear was normal. There had been no rigors, but the temperature was 101°. Although there was no evidence of the existence of pus, it was resolved to cut into the tissues forming the seat of greatest pain. Chloroform was used, and an incision two inches in length was made through the soft tissues and periosteum, to the bone. Only a drop or two of pus escaped, apparently from beneath the periosteum. The effects of this incision were most satisfactory. All the unpleasant symptoms rapidly abated, and in the course of a fortnight the boy was at work again, and the incision wound almost healed.—*Popular Science News*, March, 1888.

New Eye and Ear Hospital.

Articles of incorporation have been secured for the New Amsterdam Eye and Ear Hospital of New York. Dr. Pooley, who was for fifteen years the first assistant surgeon of the New York Ophthalmic and Aural Institute founded by Dr. Knapp, is the executive surgeon in charge of the new hospital. It is expected to open in a short time. The hospital is to be supported entirely by voluntary contributions.—*Evening Post*, May 4, 1888.

Western Pennsylvania Medical College.

The annual commencement of the Western Pennsylvania Medical College was held on March 24, and thirty-four men were graduated as physicians. A collation was served to the graduating class in the evening by the Faculty and alumni. This commencement closes the second successful year of this college.

University of Pennsylvania.

The one hundred and fourteenth annual commencement of the Department of Medicine and Dentistry of the University of Pennsylvania took place May 2, at the Academy of Music. Prayer was offered by Bishop Whitaker, after which Provost Pepper conferred the degree of Doctor of Medicine on 114 graduates, and the degree of Doctor of Dentistry on 56 graduates. This was followed by the valedictory address, delivered by Dr. John Ashhurst, Jr., Professor of Clinical Surgery. A portrait of Professor R. A. F. Penrose was presented to the Board of Trustees by Dr. N. H. Hall, on behalf of the graduating class. Dr. James H. Hutchinson responded for the trustees.

The following prizes were awarded:

The Alumni Prize of $50, to the graduate who attains the highest general average in examination, to William T. Sharpless, of West Chester, Pa.

Medical News Prize of $100, for the best thesis, divided between John L. Hatch, of Rochester, N. Y., and Seneca Egbert, of Franklin, Pa.; distinguished mention to Adolfo Ferrer Leon, of Tabasco, Mexico.

Morbid Anatomy Prize of a Zentmayer's histological microscope, for best thesis on any subject connected with pathology, to Casper Wistar Sharples, of Eugene City, Oregon.

Demonstrators' Prize, $30, by Dr. John B. Deaver, Demonstrator of Anatomy, for best record of anomalies found in the dissecting room, to John T. Green, of Easton, Pa.

The following prizes were awarded by Dr. J. William White, Demonstrator of Surgery:

First Year Prizes—Proficiency in bandaging: First, Edward Strayer, a copy of "Agnew's Surgery;" second, Wesley A. Anders, a copy of "Ashhurst's Surgery." Honorable mention was made of S. P. Eagleton, John P. Frishmuth, Edward Kerr, Thomas P. Tyson, J. D. Webster.

Third Year Prizes — For proficiency in bandaging and in operatic surgery: First, "Agnew's Surgery," to Frank P. Lenahan; second, White's pocket case of surgical instruments, to Charles Walter. Honorable mention of John T. Green, Frank N. Yeager, W. T. Sharpless, A. Livingston Stavely, Shepard Voorhees, Robert G. Le Conte, C. W. Sharples, Frank H. Harding.

NEWS.

—Dr. Charles McBurney has been appointed visiting surgeon to Roosevelt Hospital, New York, in place of Dr. Sands, who has resigned.

—It is announced that Dr. Frank Woodbury has retired from the management of the *Philadelphia Medical Times*, which will hereafter be conducted by Dr. W. F. Waugh.

—Dr. Charles E. Simmons has made a claim upon the Tilden estate of $143,350 for medical attendance upon the late Samuel J. Tilden, from 1879 up to the time of his death, a period covering nearly eight years.

—The Cincinnati *Lancet-Clinic* is publishing a daily edition during the session of the American Medical Association, in Cincinnati.

—Dr. Howard A. Kelly and Dr. Barton Cooke Hirst have been elected Associate Professors of Obstetrics in the Medical Department of the University of Pennsylvania. They will jointly occupy the chair made vacant by Prof. Penrose's resignation.

—The State Convention of Homœopathists in Kansas City passed a resolution requesting Governor Moorehouse to remove from the State Board of Health Mr. George M. Cox, of Springfield, Mo., who achieved some notoriety some time ago by attacking a woman in a hack and throwing vitriol in her face.

—All the druggists of Davenport, Iowa, have united in giving formal notice that after April 30, they will not sell or dispense any alcoholic liquor of any kind for any purpose whatever. They have been advised that the conditions of the prohibitory law passed by the last General Assembly are such that business cannot be done without violating it. There are, however, some two hundred saloons still openly doing business in Davenport, besides some wholesale liquor houses.

—The Medico-Legal Society of New York has decided to hold an International Congress of Medical Jurisprudence, at which representatives from all countries will be invited to attend and contribute papers. The Congress will hold a session of four days some time next year. Members of the Medico-Legal Society will entertain as guests all foreign visitors, and arrangements will be made for reduced rates of ocean and railway travel for those who attend from a distance.

The Chairman of the Sub-Committee, Mr. Moritz Ellinger, is the Corresponding Secretary of the Medico-Legal Society.

HUMOR.

Mrs. Society—"What a lovely baby that is we just passed." Mrs. Fashion—"Yes; it is mine." "Indeed!" "Oh, I'm sure of it; I recognized the nurse."—*Observer.*

Surgeon's wife—"How is the walking out to-day, my dear?" Physician—"Beautiful, beautiful; the pavements are full of banana skins!" "Ha! ha! beautiful," echoes the reporter on the hunt for items.

"Ma, de fiziology say yer dat de human body am imposed of free-fourth watah!" "Waal, yo' bettah mosey off to school, an' git outen dat hot sun, ur fust ting yo' know yo' be vaporatin'."—*Harper's Bazar.*

Miss Clara—"Oh, Ethel, I had my ears pierced to-day!" Miss Ethel—"Weren't you dreadfully frightened?" Miss Clara—"A little at first, but I kept saying 'solitaire,' 'solitaire,' 'solitaire,' to myself, and before I knew it it was all over."

"Only think," exclaimed Fenderson, reading of the devastations of the locusts at the West, "last summer they ate up every green thing." "What a fortunate escape!" said Fogg; "you were thinking of going out that way last spring, I believe."

Judge to a prisoner—"Are you married?" Prisoner—"Yes." Judge—"To whom?" Prisoner—"To a woman." Judge—"Of course; that goes without saying." Prisoner—"Oh, no, your honor; for there's my sister; she is married to a man!"

Curious Request for Medical Services.—A subscriber to the Reporter sends us the following request from a young colored man who wished to have his chest examined:

"I acquire your physitiancy to examine my personal, and oblige.

Respectfully, * * * *"

An impertinent lawyer was arguing a case involving manorial law before Lord Mansfield. Said he, "My Lord, I happen to know a good deal about this subject, for I have two little manors myself." "Yes," interposed his lordship, "I have frequently noticed that."—*American Druggist.*

Studying the Weather.—"Mamma," said a pretty young thing in her new spring street costume, "have you the morning paper?" "No, Clara; your papa took it down town with him. There is yesterday's morning paper on the table." "Oh, that will do just as well. I only want to look at the weather probabilities."—*Puck.*

OBITUARY.

ISAAC PURSELL, M. D.

Dr. Isaac Pursell was born near Easton, Pa., September 19, 1823. When a child his parents moved to Phillipsburg, N. J., or rather to a farm near there. He studied medicine with Dr. Wilson, of Bethlehem, Pa., and was graduated from the University of Pennsylvania. He first began the practice of medicine at Rushtown, Pa., near Danville, where he married Miss Delia, daughter of Colonel Scott. Shortly after he removed to Berrysburg, Pa., thence to Shamokin, in 1858, and in 1861 to Danville, where he remained until the date of his death. He became a member of the Pennsylvania State Medical Society in 1874, and later of the American Medical Association, to both of which associations he was warmly attached, and the annual gatherings of which, until within two or three years of his death, he greatly delighted to attend.

The writer of this sketch became a student in Dr. Pursell's office, at Berrysburg, and has been in close correspondence with him ever since. He was a careful and conscientious practitioner of medicine, one who carried good cheer and sunshine wherever he went, and his professional visits were a benefit to his patients. He enjoyed a large general practice, which he kept up until a short time before his death. He was the soul of honor professionally, was modest and unassuming in his manners, never paraded his professional qualifications, and heartily detested shams of all kinds, whether in medicine, politics or religion. He was a consistent Christian, and an earnest and pronounced advocate of temperance. He died at his home in Danville, March 27, 1888, of cerebral apoplexy, after a few hours illness. J. F. K.

J. FORD PRIOLEAU, M.D.

Dr. J. Ford Prioleau, of Charleston, S. C., died at Beaufort, April 11, at the age of 62 years. He was graduated from the Medical College of the State of South Carolina in 1847, and in 1871 he became professor of obstetrics in the same institution. In 1881 he was made Dean of the college, and held that position until the time of his death.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from April 22, 1888, to April 28, 1888:

Lieutenant-Colonel Jos. C. Bailey, Assistant Medical Purveyor, granted leave of absence for twenty days on surgeon's certificate of disability, with permission to apply for an extension. S. O. 92, A. G. O., April 21, 1888.

Lieutenant Colonel Jos. C. Bailey, Assistant Medical Purveyor, will transfer the public funds, for which he is responsible, and the charge of the medical purveying department in New York City, temporarily, to Capt. Henry Johnson, Medical Storekeeper. S. O. 92, A. G. O., April 21, 1888.

Par. 13, S. O. 89, A. G. O., April 18, is revoked by par. 1. S. O. 93, A. G. O., April 23, and Major Geo. M. Sternberg, Surgeon, U. S. Army, is directed to proceed to the Island of Cuba for the purpose named in the letter of the President addressed to the Secretary of War on the 17th inst.; upon the completion of this duty will return to his proper station, and submit his report to the President on or before June 25, 1888.

Major R. S. Vickery, Surgeon, granted leave of absence for four months, with permission to apply for an extension of two months, and to go beyond sea. S. O. 95, A. G. O., April 25, 1888.

By direction of the President, Surgeon Remus C. Persons, U. S. Navy, is assigned, temporarily, to the charge of the Army and Navy General Hospital, Hot Springs, Ark., during the absence, on leave of Major R. S. Vickery, Surgeon U. S. Army, Surgeon in charge. S. O. 96, A. G. O., April 26, 1888.

First Lieutenant Leonard Wood, Assistant Surgeon, granted one month's leave of absence, with permission to apply for an extension of two months. S. O. 41, Dept. Ariz., April 18, 1888.

First Lieutenant L. G. Anderson, Assistant Surgeon, granted one month's leave of absence from June 1, 1888. Resignation accepted by the President, to take effect July 1, 1888. S. O. 92, A. G. O., April 21, 1888.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from April 29, 1888 to May 5, 1888:

Capt. A. A. De Loffre, Assistant Surgeon, granted leave of absence for six months on surgeon's certificate of disability, with permission to go beyond sea. S. O. 99, A. G. O., April 30, 1888.

First Lieutenant Guy L. Edie, Assistant Surgeon, now under orders to report for duty to the commanding officer, Fort Douglas, U. T.; will accompany the 8th Cavalry from Dept. of Texas to Dept. Dakota, and upon completion of this duty will proceed to Fort Douglas. S. O. 99, A. G. O., April 30, 1888.

First Lieutenant Wm. D. McCaw, Assistant Surgeon, relieved from duty at Fort Leavenworth, Kan., and ordered for duty at Fort Crawford, Col. S. O. 48, Dept. Missouri, May 1, 1888.

First Lieutenant Ogden Rafferty, Assistant Surgeon (recently appointed), ordered for duty at Fort Clark, Tex.

Capt. John V. Lauderdale, Assistant Surgeon, ordered from Fort Clark, Tex., to Fort Davis, Tex. S. O. 98, A. G. O., April 28, 1888.

Changes in the Medical Corps of the Navy for the week ending May 5, 1888:

Medical Director W. T. Hord and Surgeon T. Woolverton, ordered as delegates to represent the Medical Department of the Navy at the meeting of the American Medical Association, May 8, at Cincinnati, Ohio.

Surgeon Geo. P. Bradley, ordered to Navy Yard, Brooklyn, N. Y., without delay.

WHOLE No. 1629.] MAY 19, 1888. [VOL. LVIII, No. 20.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

SOMETHING NEW.

ELIXIR OF COCA AND CALISAYA

which represents the virtues of these drugs in a *most active and palatable form.* The process of manufacture is ENTIRELY ORIGINAL—that of direct fermentation from the bark and leaf—and we claim that better results can be obtained from this preparation than from any other combination of *Coca and Calisaya* now made.

Clinical Lecture.

CRETINISM: CASES PRESENTING TREMOR AS A SYMPTOM WITH THE EXHIBITION OF A PATIENT SHOWING SYMPTOMS OF PARA-MYOCLONUS MULTIPLEX.

BY JAMES HENDRIE LLOYD, M.D.,

PHYSICIAN TO THE PHILADELPHIA HOSPITAL AND INSTRUCTOR IN ELECTRO-THERAPEUTICS IN THE UNIVERSITY OF PENNSYLVANIA.

Reported by William H. Morrison, M.D.

Gentlemen: In the previous lectures which I have had the pleasure of delivering before you, I have dealt entirely with the subject of insanity, which is a failure or perversion of mental power or faculties, the result of change or disease coming on in later life, that is, either in adolescence or adult life. There is another great division of mental impairment which is termed idiocy, and of which we have very marked specimens in this hospital. Idiocy may be defined to be a failure, or more properly a lack of development, of mental faculties dating from a period before birth or previous to the period of normal development of the child's intellectual faculties. All idiots are not necessarily congenital idiots, although the affection must date from early childhood before the brain has become developed.

It is not my intention to attempt to-day to cover such an extensive subject as idiocy. There are many forms, and they have been classified by Dr. Ireland in ten divisions. He speaks of (1) the genesic idiot, that is one born so; (2) of the eclampsic or (3) epileptic form, that is those which exhibit epileptic seizures; (4) the paralytic; (5) traumatic or (6) inflammatory, or those in which the idiocy depends upon some accident either after birth or at the period of birth. It is important that the general practitioner should remember that in a certain proportion of cases the idiocy is due to accidents during labor, either by prolonged labor, by some resistance in the maternal soft parts, some defect in the pelvic canal, or by the use of the obstetric forceps. I have no doubt that some cases of idiocy are due to the use of the forceps, sometimes unavoidably so. These cases of paralytic or traumatic idiocy are often accompanied, as the name indicates, by paralytic phenomena. There is often hemiplegia, and not infrequently certain abnormalities in the shape of the head, such as flattening of the forehead or crushing in of the side of the head. I have seen several such instances. We have next, according to Dr. Ireland's classification, the (7) micro-cephalic and the (8) hydro-cephalic types of idiocy. The first form in which the head is smaller than normal is always congenital. Any case in which the circumference is less than eighteen inches is regarded as micro-cephalic. Some, in fact, go far below this, even as low as thirteen inches. The appearance of these cases is very characteristic. You have all seen instances of the hydro-cephalic idiot, although all patients with hydocephalus are not necessarily idiots. We next have (9) idiots by deprivation of the senses; that is, those born without the ordinary avenues of sensation. One of the most interesting examples of this group was Laura Bridgeman, whose case was described by Dickens. She was deaf, dumb and blind. She was, however, carefully educated by her instructor. I think that she was, properly speaking, not an idiot. We have then (10) the last division. These are the cretins and cretinoid idiots, and it is to this class that I wish to call particular attention.

Cretinism.

It so happens that we have in this hospital one of the best illustrations of the cretinoid idiot which it is possible to find on this continent, where pure cretinism is not endemic, and where we have only occasional sporadic cases. This man, for so he is, although no taller than a child of four or five years of age, is 29 years old, and has been an inmate of this hospital for many years. With reference to cretinism, it presents certain very distinct and special characteristics which are not found in other forms of idiocy. As you all know there is a form of this affection known as endemic cretinism, found especially in certain mountainous regions, as the Alps and Pyrenees in Europe, and the Cordilleras mountains in this hemisphere. We have practically nothing of it in the United States. Cretins as found in the Alpine villages are, in their worst forms, not unlike the individual before us. The cretin is stunted in stature, he is very deficient in intellect, he usually has a much enlarged thyroid gland, which is not the case in this instance, and he has a peculiar and typical physiognomy which we see to a certain extent in this case. The bridge of the nose is much sunken in and the nostrils flattened out; the eyes are widely separated, with an almost translucent appearance of the structures about the eyes. The lips are thick and large, the mouth constantly open, the hypertrophied tongue protrudes. There is also a tendency to slobber. Cretins also have a peculiarly white or rather a waxy appearance of the skin. The skin is apt to be hypertrophied and scaly. The hands are large, flabby and spade-like. The abdomen is protuding. The sexual apparatus is often undeveloped. The limbs are very short and covered with poorly-developed muscles. There are all degrees of endemic cretinism, varying from a severe form up to one in which there are very slight evidences of the dyscrasia.

There are several interesting questions connected with this subject, especially with reference to goitre and that peculiar condition known as myxœdema. This is a very obscure subject on which I am able to throw very little light. I can only indicate what is known about it. These cases of endemic cretinism as seen in mountainous regions are usually accompanied with enlargement of the thyroid gland. We have also cases of sporadic cretinism, of which this case is an example, as he was born in Philadelphia, in which the enlargement of the thyroid gland is usually absent. There is in fact in most of the sporadic cases, no evidence of the presence of a thyroid gland. I suppose that in the present instance not a vestige of the thyroid gland would be found on dissection. There are, however, certain accumulations of tissue over the clavicles which form distinct masses and are very characteristic of sporadic cretinism. The condition known as as mxyœdema is allied to cretinism. It is a hypertrophy of the subcutaneous connective tissue in the meshes of which is a product known as mucin. There has been observed a certain relation between this condition of myxœdema and enlargement of the thyroid gland. They, as it were, counter-balance one another. Where there is enlargement of the thyroid gland, it seems as though the whole force of the dyscrasia was spent in this way, whereas in cases in which there is not this hypertrophy, the condition myxœdema is present. This is of much practical importance especially to surgeons. It was discovered sometime ago by Horsley, of London, that if the thyroid glands of monkeys are removed, a condition of myxœdema is likely to appear, and the animals also present the characteristic cretinoid physiognomy. What the relation between these two conditions is, has not been thoroughly elucidated; I can only state the facts. As I have said this is of importance to the surgeon, who is sometimes called upon to extirpate the thyroid gland. I do not know whether or not the destruction of the gland by galvanic puncture would tend to induce this condition of myxœdema. It would, however, be a great misfortune for the patient to exchange her goitre for a condition of myxœdematous degeneration.

Very little is known with reference to the true pathology of cretinism. There are, however, one or two views brought forward by those who have especially investigated the subject, and to these I wish briefly to call attention. It is found on dissection in all cases of cretinism, that they present to a marked degree what is known as basilar synostosis, that is to say, early ossification of the cartilage, which normally exists in early life between the body of the sphenoid bone and the basilar process of the occipital bone.

I shall next call attention to one or two features presented by this case. The enlargements over the clavicles are very characteristic. You note the coarse hair, the widely separated eyes, the large increase of tissue about the eyes, the thick lips and constantly protruding tongue. The man's eyesight is very poor; his intelligence is very low, but he probably knows more than we would give him credit for from his appearance. He shows often to those familiar with him that

he does take notice and does remember. You observe the protruding abdomen, and the small, crooked legs. He can walk a little, but he does not do it unless compelled to. His sexual organs are those of a boy three or four years old. Another feature is his utterly apathetic condition, the purely vegetative life which he leads. As you see him here, so he sits all day long. He interests himself in nothing, and requires nothing to amuse him. He has very few accomplishments; the only two which I recall are that he can swear like a tramp and kiss his hand to the ladies. His range of words is limited, but he seems to understand most that is said to him.

One more word with reference to the anatomical condition in this affection. It is almost invariably, if not invariably, found that there is this premature synostosis or alteration in the cartilage between the body of the sphenoid and the basilar process of the occipital bone, and it has been supposed that this is the cause of this peculiar state. Whether or not this is the case, we cannot be positive. It was Virchow, I believe, who originally demonstrated the existence of this anatomical condition. It is conjoined with premature ossification of the epiphyses of the long bones, helping to produce the dwarfed condition of the limbs, which is seen in cretinism.

Cases Presenting Tremor as a Symptom with the Exhibition of a Patient Showing Symptoms of Paramyoclonus Multiplex.

I shall now call your attention to certain forms of tremor and myoclonic disorder—a very wide and interesting subject. The whole subject of tremor, ataxia, irregular spasm, and local convulsion unaccompanied with loss of consciousness, presents numerous difficulties to clinical pathological study. We have succeeded in differentiating certain varieties of these into well-marked forms of disease. For instance we have the pure and simple chorea, the chorea of childhood, the disease known as Sydenham's chorea, which can usually be diagnosed without difficulty. We have, however, other forms, approaching the choreic form which are not so easily diagnosticated, and the pathological conditions underlying which present many difficulties and mysteries. Besides chorea, there are some other forms of motor disorder which are not difficult to recognize. Among these we have Parkinson's disease or paralysis agitans. Then we have tremor depending upon change in the nervous structures, which is termed disseminated sclerosis or sclerosis in plaques.

The three patients now before you represent to a certain extent these three forms of motor disorder. The first case can be dismissed with a very few words. This woman is suffering with paralysis agitans, an affection which was first described by Parkinson in 1817. I want you to note that the arms and limbs, and the forearms more especially, are in a condition of constant tremor, which presents certain characteristics not seen in any other form of tremulous disorder. In the first place the tremor is constant during the absence of voluntary motion. The character of the tremor also is peculiar, and has not I think been sufficiently dwelt upon in considering the differential diagnosis of these cases. There is a distinct rhythmical movement of the forearms, which is dependent upon alternate action of the flexors and extensors. This movement is gentle, limited in range and not incoördinate. In the earlier stages of this affection, and usually only in the early stages, the patient is able to control this spasmodic condition by voluntary movement. This is mentioned by many as one of the diagnostic points, but it does not hold in all cases, and especially is this true in the advanced cases. It is usually stated that patients suffering with paralysis agitans are able to write, that when the voluntary impulse is sent out through the nerves, the muscles are steadied and for a short time the spasm is stopped. In the present case the attempt to write has very little effect on the spasmodic movements.

This second case is interesting for two or three reasons. This man is afflicted with irregular spasms of the muscles of the face, neck, trunk, arms and legs. These spasmodic contractions are wide in range, causing the patient to gesticulate, squirm and grimace in a grotesque and conspicuous manner. He has but little control over these motions; and they continue incessantly during the absence of voluntary movement. If you saw a child of ten years of age exhibiting such movements, you would at once say that it was a case of chorea. This patient, however, is rather more advanced in years than is usual for the development of chorea. There is also a distinct family history of this disorder. You notice the difference between the movements of this man and those of the woman to whom I have called attention. She has the constant rhythmical spasms of paralysis agitans; he has the incoördinate action of the muscles of the arms known as chorea. I might state here that in paralysis agitans, the muscles of the neck are

rarely involved. The tremulous motion of the head is due to the shaking of the body from the tremor of the extremities. In this man there is marked movement of the muscles of the neck. We have tried to reach some other diagnosis in this case than chorea. I thought at one time that there was a degree of ataxia which might warrant a diagnosis of one of the ataxic states. I am now inclined to think that it is a case of chorea, depending in some peculiar way upon hereditary taint. What that is I am unable to say. I do not recall having ever heard such a distinct family history of chorea as this man gives us. The patient tells us that his grandfather, and two of his father's brothers had this condition. One paternal aunt suffered in the same way. His aunt married and raised a family of children before the trouble appeared. The patient's father died young, and never suffered with this affection. As far as the patient knows, none of the family had fits. He, himself, never had chorea when young so far as I am able to determine. His present age is 43 years, and the trouble began seven years ago.

This case presents decided distinctions from the ordinary chorea of childhood. Chorea of childhood is not an hereditary affection. As you have heard this man has given a distinct history of the affection coming on in other members of the family in adult life. The patient was himself 36 years of age when the disease appeared. This condition seems not to be amenable to treatment. He has been given the ordinary specific remedies for chorea without effect. What underlies this condition is a subject for speculation. It was at one time thought that this might be a case of what is known as Friedreich's disease, which affection might be called hereditary locomotor ataxia. It comes on within a few years after birth and consists of a congenital lack of development, producing early degeneration of the lateral tracts together with the posterior columns of the cord. This leads to a form of ataxia not unlike locomotor ataxia. Such cases, however, do not have the lancinating pains and the lesions of sensation that are seen in locomotor ataxia. This patient evidently does not belong to this class.

This colored boy, the last case which I shall show you, is by far the most interesting of all. In the effort to differentiate these conditions, there has been mapped out by neurological writers a certain indistinct type of disease which has been called *para-myoclonus multiplex*. This term means a more or less universal clonic spasm of the muscles. This affection also was first described by Friedreich. I have brought this colored boy before you to-day to serve as a text for a few remarks upon this affection. He presents certain multiplex myoclonic phenomena to a marked degree, although I am disposed to think that there is some organic change in the cord, such as disseminated sclerosis, to account for the condition present. Friedreich described the first case of this disease reported, that of a patient fifty years of age suffering with phthisis, who after a severe shock suffered for some time with a condition of almost tetanic rigidity. This was followed by a condition of clonic spasms in the muscles of the arms, the trunk and the limbs, varying in rapidity from ten to fifty per minute. These clonic spasms continued more or less persistent until the death of the patient from the disease of the lungs. I believe that at one time they were partially relieved by the galvanic current. Several other observers have since then put on record cases of a similar character. These cases were unassociated with any loss of consciousness. The peculiar clonic conditions have not been exactly alike in all the cases reported, and they probably differ in their causes and pathology. In some the clonic spasms have been paroxysmal. Hammond has described a condition of convulsive tremor, more or less closely allied to this condition, but in which the spasms occur in paroxysms, the patient having immunity for a long period of time. Some of these cases are much worse on voluntary movement, while others are made better. In some of these cases there is associated a more or less tetanic condition.

In the present case there are three distinct forms of movement. As he sits before you, you will notice a choreiform movement of the muscles of the arms and of the trunk, which is constant, and not associated with voluntary movement. There is another variety of movement which is seen in certain forms of mental weakness and imbecility, and also occasionally in hysteria and hypochondriasis, which is a peculiar acquired movement. He has a curious habit of slapping one hand on the other when a little agitated and when talking. Neither of these movements is of the nature of pure myoclonus. When talking you observe that he has one or two set expressions which he always uses. His intellectual capacity is not very great. Every time that he speaks he exhibits this automatic movement of one hand upon the other. This is not choreic.

He has still another interesting form of motor disturbance. When he puts his feet

upon the floor and attempts to walk, his legs are thrown into a more or less tetanic or rigid condition, which is not a true spastic spasm, but consists of a series of clonic contractions of the muscles of the thighs. This is especially well marked when he attempts to sit down. The patellar reflexes are decidedly increased. The slightest tap over the patellar tendon causes a very marked contraction of the quadriceps. There seems to be no ankle-clonus.

The facts which have made the strongest impression upon my mind are that these three types of movement are presented in one case, and that the condition of the lower limbs is the one which is more distinctly related to these multiplex myoclonic phenomena than I have ever seen it before. As in many other cases in this hospital, we have been unable to obtain much history of this patient. As far as we can make out this condition has come on within the last two or three years. It is not associated with other evidences of degeneration of the central nervous system. There are no areas of anæsthesia. The eyes have been examined by Dr. De Schweinitz, and no appreciable alteration in the eye-ground found. I think that in this case, the diagnosis lies between some form of disseminated sclerosis and the motor phenomena described under the head of para-myoclonus multiplex.

In a certain number of cases we have a degeneration of the central nervous system known as disseminated sclerosis or sclerosis in plaques. In this affection there are little islets of degeneration over the cortex, and involving more or less the other structures of the brain and extending downward into the cord. This produces a special alteration of motility which is to be diagnosed from the other conditions already referred to. In this affection we have, especially in the arms, a degree of ataxia which it is necessary to differentiate from paralysis agitans. In the latter we have the peculiar rhythmical character of the spasm, and the fact that it is more or less controlled by the will. In disseminated sclerosis we have just the opposite. When the patient attempts to make a voluntary movement the motor impulses passing down the lateral columns of the cord are more or less broken up and interrupted by these islets of degeneration. As a consequence we have a series of spasmodic movements which are more ataxic in character than choreic, and which have not the rhythmical character seen in paralysis agitans. It so happens that in this form of disseminated sclerosis these islets become more and more numerous in the cord, and set up in the lateral columns a process of degeneration running down the motor tracts of the cord. The result is that while we still have this condition of ataxic jerking movement in the arms, we are apt to have in the lower limbs a condition of spastic paraplegia. This man has more or less of this condition. He has what is very characteristic of disseminated sclerosis —marked increase in the patellar reflexes. I feel somewhat in doubt about the diagnosis, because in his arms he does not present the characteristic conditions of disseminated sclerosis. He has not the jerking movement of this affection. He has, however, this constant choreiform movement entirely independent of volition. I should call it a case presenting rare multiplex myoclonic symptoms, probably the expression of an insular degeneration in the central nervous system.

Communications.

TREATMENT OF PLACENTA PREVIA. A HISTORICAL AND CRITICAL SKETCH.[1]

BY CHARLES P. NOBLE, M.D.,
SENIOR ASSISTANT PHYSICIAN, PHILADELPHIA LYING-IN CHARITY.

Placenta previa occurs so rarely that the practitioner is especially dependent upon the literature of the subject for the foundation principles upon which to base successful treatment. The frequency of its occurrence is variously estimated by authors.

Johnson and Sinclair,[2] of the Rotunda Hospital, gave it as 1 in 573; Schuey,[3] 1 in 1564, among 519,728 labors in the Grand Duchy of Hesse; Müller,[3] 1 in 1078, based on 876,432 births; Lomer,[3] at least 1 in 723 deliveries in Berlin.

The placenta is said to be previa "when it is attached to any portion of the uterus which is subject to distention during labor" (Lusk). Placenta previa is central or complete when only placenta can be felt after dilatation of the internal os. It is partial or incomplete, when after dilatation of the os, the membranes as well as the placenta can be felt. It is marginal, when the placental border reaches the internal os; and lateral, when attached within the zone of distention, but where the placental border does not extend to the inner os.

[1] Arranged from a paper read before the Northern Medical Association of Philadelphia, April 13, 1888.

[3] Lomer, *Am. Jour. Obstet.*, Vol. XVII, p. 1248.

Lateral implantation is often an unrecognized cause of so-called accidental hemorrhage. The amount of hemorrhage and the mortality vary with the variety of placental insertion. It is generally admitted that the source of hemorrhage in placenta previa is the lacerated utero-placental vessels. Mackenzie[1] in a series of experiments on pregnant bitches, where he partially detached the placenta, demonstrated that the blood flowed from the bared uterine wall, and not from the surface of the placenta. The abandonment of the teaching of Hamilton and Simpson that the source of the hemorrhage was from the partially separated placenta, has greatly influenced modern practice.

Various explanations have been given as to the cause of hemorrhage during pregnancy. The first theory was that obliteration of the cervical canal by being drawn up into the cavity of the body of the womb in the later months caused a spreading out of the internal os, and partial separation of the placental attachments. This was naturally abandoned as being generally applicable, when it was shown that the supposed shortening of the cervical canal did not occur at all, or only in the last weeks of gestation.

The theories of Jacquemier and Barnes as to the relative frequency of growth of the placenta and uterine wall, must likewise be abandoned. For not only are they diametrically opposite, but also they are negatived by the fact that cases of placenta previa frequently go to term without hemorrhage; were either true, hemorrhage would be inevitable during the last three months of pregnancy.

They are further opposed by the admitted observation that placenta previa is a not uncommon cause of abortion. Finally, Matthews Duncan[2] asserts that the causes are the same as where hemorrhage occurs during gestation with a normal insertion of the placenta; that while its occurrence is favored by the abnormal position of the placenta, it is a purely accidental phenomenon, and in no sense inevitable. This view is favored by the fact that it not uncommonly does not occur till labor at term. Aside from occasional rupture of a vessel, and partial separation of the placenta from blows, jerks and falls, hemorrhage may at any time take place from detachment, brought about by uterine contractions. That intermittent uterine contractions are present from an early period of pregnancy, has been shown by Braxton Hicks,[1] and is universally admitted. And as Playfair[2] observes, "there is no reason to suppose that these contractions do not affect the cervical, as well as the fundal portions of the uterus; and in cases where the placenta is situated partially or entirely over the os, one or more stronger contractions than usual may at any moment produce laceration in that neighborhood." This view is accepted by Spiegelberg and King,[3] and certainly best accords with the various conditions.

During labor, hemorrhage is caused by the loss of relation from dilatation of the os and lower uterine segment. But even here it is not inevitable. "Although," says Cazeaux, "hemorrhage is usually considered to be inevitable under such circumstances, yet it may not appear even during labor; and the dilatation of the os uteri may be affected without the loss of a drop of blood." A recent case of my own substantiates this, for while interference was not used until the head was on the perineum, yet the labor was concluded without the loss of blood. Hemorrhage is apt to be less where the fetus has been dead for some time, so that retrograde changes have occurred in the utero-placental vessels. Simpson has shown that where the placenta is expelled before the birth of the child, hemorrhage generally ceases. The investigations of Barnes and Duncan satisfactorily explain these cases. Barnes has demonstrated that separation need only occur for a certain distance within the os; after which, with strong uterine contractions to seal up the mouths of the torn vessels, hemorrhage ceases; that hemorrhage ceases after complete detachment, not because it is complete, but because it is detached from the area of dangerous implantation; that in the cases where hemorrhage is absent, the pains have been sufficiently strong to separate the placenta from the cervical zone before flooding occurs. Strong contractions are necessary to prevent subsequent hemorrhage. Some of these cases may be explained upon the ground that in the region of the os at term, intimate vascular connections do not exist. I am sure that this was true of my case already referred to.

The prognosis is variously stated. It depends largely upon the degree of implantation, and also upon the method of treatment. According to Lusk, one mother out of four dies during or shortly after delivery, and nearly two out of three children are born

dead. Including deaths from puerperal processes, Müller[1] (1877) estimates the maternal mortality at from 36 to 40 per cent. Among 4,164 cases, collected by Charpentier, Depaul, Simpson, Schwarz, Trask, Müller and King,[1] there were 1,045 deaths—25 per cent. Individual operators have secured better results. Thus: Spiegelberg 102, 16 deaths, 16 per cent.; Barnes 69, 6 deaths, 8.5 per cent.; Hecker 70, 7 deaths, 10 per cent.; Müller 15, no deaths; Hofmeier 37, 1 death, 2.6 per cent.; Behm 40, no deaths; Lomer[2] 16, no deaths; Murphy[3] 23, no deaths; E. Wilson[4] 30, 2 deaths, 6.6 per cent. Nine operators had 402 cases, 32 maternal deaths, 7.9 per cent.

The prognosis for the child is much worse, and as will appear later, no method of treatment materially improves its chances. Authors give it as follows: Schwarz, 75 per cent.; Barnes, 64 per cent.; Müller (average of 2,360 cases), 64 per cent.; Spiegelberg and Braun, 50 per cent.; Lomer,[5] Hofmeier and Behm (178 cases), 60 per cent.; Murphy[3] (23 cases), 57 per cent.; King,[6] 57 per cent. (Partial placenta previa, 41 per cent.; complete, 66 per cent.)

Placenta previa has been recognized as a complication of labor since 1685, when Portal wrote on the subject. Levret, Smellie, Roederer, Rigby, Barnes, Braxton Hicks, Greenhalgh, Thomas and Murphy may be mentioned as prominent among those who have contributed to a knowledge of its nature and treatment.

Treatment.—King[7] reports 33 cases where no treatment was used. In 11, there was complete, in 11, partial placental presentation, and in 11 this was not noted. In 14, the hemorrhage was moderate; in 6, profuse; in 13, not reported. The maternal mortality was 33 per cent.; fetal, 58 per cent.

Accouchement forcé.—One of the oldest methods of treatment is that of forced delivery. One or two fingers were inserted through the os, then the entire hand, after which the fetus was turned and rapidly extracted. Contusions and lacerations of the cervix were inevitable[8], and the result so deplorable that the method was and is universally condemned. Müller[1] reports 92 cases of *accouchement forcé* followed by version, with a maternal mortality of 47.8 per cent.; fetal, 62.7 per cent.

Rupture of the Membranes.—This measure was proposed by Puzos. It is claimed for the method that by evacuating the liquor amnii it stimulates the uterus to contract, and thus arrests hemorrhage. It has the endorsement, among other modern authorities, of Barnes and Playfair.

Barnes[2] says that "the puncture of the membranes is the *first thing* to be done in all cases of flooding sufficient to cause anxiety before labor." But as King,[3] Müller and Lomer[4] have shown, in a considerable percentage of cases, hemorrhage does not cease after the manœuvre—a serious matter where the membranes have been ruptured with an undilated os. It is now difficult or impossible to do combined version. The ovum no longer acts as an internal tampon, and concealed hemorrhage is apt to occur if the vaginal tampon is employed as is advised.[5] Hemorrhage ceases most often after rupture of the membranes, in cases of partial or lateral implantation. Shroeder, Cazeaux, King[6] and Murphy,[7] advise rupture only after a certain amount of dilatation. Hence, we may conclude that rupture should not be practiced early, except as a step in Braxton Hicks' method. King[8] reports 24 cases, with a maternal mortality of 8 per cent.; fetal, 42 per cent. Fourteen of these were cases of partial placenta previa, and in only nine was the hemorrhage severe. The two maternal deaths he ascribes to early rupture of the membranes.

The Tampon.—Leroux is usually credited with introducing the tampon treatment in 1776; but according to Parvin,[9] this author mentions no instance of its use in placenta previa, and to Wigand must be given the honor.[10] Wigand did not use the tampon

[9] *L. c.*, p. 321.
[10] As bearing upon this point, the following quotation from Rigby's Midwifery (The Library of Medicine, by A. Tweedy, Vol. vi., p. 260) is of interest: "If, after the commencement of a flooding we favor the formation of a coagulum by means of a plug, are we not aiding nature? It brings on labor much sooner, and the os uteri has time to dilate without further loss of blood."—(Leroux, *sur les Pertes de Sang*, § 309.)

exclusively, as exceptions, he says: "It cannot be applied with women whose birth-passage is so irritable that they cannot retain the tampon, even for the space of fifty minutes; so, too, one would act very unreasonably, and even criminally, were he to use the method when called to a woman who had bled almost to death." [1]

Wigand states that he saved all the mothers and children where he used the tampon. This statement, together with his references to feeling the bag of waters, would indicate that he was not dealing with cases of central implantation. Certainly no one's results since, have equalled his. The tampon and internal version have been the methods in most general use during this century. Besides the classical tampon the followers of Barnes have used his hydrostatic dilators, which have the advantage of dilating the os while restraining hemorrhage, and the Vienna school under Karl Braun have largely employed his colpeurynter. The colpeurynter is useful to dilate the vagina in primaparæ. The object sought in the use of the tampon is to restrain hemorrhage while the os dilates. The uterine vessels are compressed by the tampon below and the ovum above, and whatever hemorrhage occurs adds to the pressure. The tampon also restrains hemorrhage by exciting uterine contractions. After dilatation is secured, delivery is effected by the natural powers, version, or the forceps. King,[2] in 75 cases reports a maternal mortality of 25 per cent.; fetal, 53 per cent., although the cases were relatively favorable. Especially where the tampon was followed by version was the result bad—34 cases, 35.7 per cent. maternal mortality; 61.7 per cent. fetal. Charpentier [3] reports 65 cases (Parisian clinic), with 35 per cent. maternal mortality. The tampon was followed by spontaneous delivery, version, or the forceps.

Ergot.—This is given by Auvard as the method of Paul Dubois. According to Parvin[4] the results of this method are a maternal mortality of 42 per cent.; fetal, 77 per cent. But while this is true where ergot is relied upon exclusively, it is not where it is given after dilatation is secured. Murphy [5] and E. Wilson both use it freely at this time, and together they had fifty-three cases with only 2 maternal and 21 fetal deaths. King's [1] table also shows that ergot is a useful adjuvant.

[1] Parvin, *l. c.*, p. 321.
[2] *L. c.*, p. 775. The general mortality was only 22 per cent.
[3] *L. c.*, p. 220.
[4] *L. c.*, p. 323.
[5] *L. c.*, p. 208.

Complete Detachment of the Placenta.—This is usually given the method of Radford and Simpson.[1] It is now purely of historical interest, since the premises upon which it was based have been proved to be false, and also because its maternal, and especially its fetal mortality was high. Simpson in 141 cases gives maternal mortality, 13.6 per cent.; fetal, 79 per cent. But Water and Trask in 94 cases had a maternal mortality of 24 per cent.; fetal, 75 per cent., and Hecker a maternal mortality of 27.5 per cent.[2] King's [3] table in 22 cases of central placenta previa gives a mortality of 18 per cent. and 77 per cent., respectively.

Podalic Version.—Since the days of Portal, until recently, internal podalic version has been resorted to in cases of alarming hemorrhage from placenta previa.[4] It was a part of the old method of forced delivery, and afterwards was used after the tampon or other method of treatment. Müller [5] collected 860 cases of internal version with a maternal mortality of 30 per cent. King,[6] 115 cases, maternal mortality 23 per cent.; fetal, 60 per cent.; in 63 cases version alone was used, mortality 22 per cent.

Forceps.—The forceps do not appear to have been largely used. They can scarcely be applied in the central variety, and dilatation is always a pre-requisite. When used within the uterus, in addition to the recognized dangers of the high operation, there is greater liability to rupture of the inferior uterine segment, from the increased vascularity present, with subsequent hemorrhage. Charpentier mentions 9 cases, with 4 maternal and 6 fetal deaths. King reports 10 cases of which 3 mothers, and 6 children died. It would seem best to reserve the forceps for those cases where the head is in the pelvic cavity, and uterine inertia is present.

The foregoing are the methods which, until recently, have been employed, singly or combined, in the treatment of placenta previa. Including all cases, all varieties of placental presentation, cases in which nature effected the delivery more or less assisted by these measures, and those in which version or the forceps were employed, the maternal

[1] Portal and Smellie both practiced this method.
[2] Charpentier, *l. c.*, p. 223.
[3] *L. c.*, p. 772.
[4] Portal had excellent results. He details fourteen cases, and lost but one mother. Besides he "had saved divers other women in the same condition in the hospitals in Paris." (Translation Compleat Practice of Men and Women Midwives, London, 1763.)
[5] Charpentier, *l. c.*, p. 221.

mortality is at least twenty-five per cent.; fetal, sixty per cent. Müller estimates that, including deaths from puerperal causes, forty per cent. of the mothers die. This mortality condemns the methods, for by others, better results can be obtained.

Fifty years ago Dr. Renton[1] said that "Portal, in 1672, knew as much on the subject of uterine hemorrhage occasioned by the displacement of the placenta from the os uteri, and the practice necessary for its suppression, as we do at the present time." Fortunately this is no longer true. Since that time there have been introduced the methods of Barnes; the induction of premature labor; Braxton Hicks' combined version, and the method of Murphy.

Barnes' Method.—Barnes wrote on placenta previa in 1847-57, and his theories and practice have changed but little since. His method is best described in his own words.[2] "1. Rupture the membranes. 2. Apply a firm binder over the uterus. 3. A plug may be applied to gain time, but it must not be trusted; watch closely. 4. Separate all the placenta that adheres within the lower zone, and observe closely. If no hemorrhage, wait awhile. The uterus may do its own work; if not dilate the cervix with the water-bags. Again pause and observe. If nature fails to deliver we resort to the forceps, which gives the best chance for the child, or turn." Dr. Barnes has reported sixty-nine cases with a maternal mortality 8.5 per cent.; fetal, 67 per cent. He makes the unfounded claim[3] that his method has saved more mothers than any other. We believe that Barnes' greatest claims to notice should be based upon his opposition to forced delivery, his teachings concerning the lower uterine segment, and his introduction of the water-bags.

Induction of Premature Labor.—In 1864, Dr. Robert Greenhalgh read a paper before the Obstetrical Society of London, entitled "Practical Remarks upon the Treatment of Placenta Previa,"[4] in which he advocated this practice. His views were accepted by Drs. Barnes, Hicks, Hewitt and Oldham. T. G. Thomas, in 1868, advocated the same practice. To these two men belong the credit of systematizing and formulating this method of managing placenta previa.[5] In 1877, Thomas wrote a paper on the subject, in which he reported eleven cases, with one maternal death from sepsis. The advantages of the method are obvious. The mother has not been drained of life's fluid by repeated hemorrhages. She is saved the mental agony of fear induced by the fearful floodings that so often occur during the last three months of pregnancy. She is ensured a medical attendant in her hour of need. Above all, her chances for recovery are increased. The infant's prospects, also, as has been amply demonstrated, are conserved by the method. The physician is enabled to have counsel or assistance, and to conduct the labor in an orderly and systematic manner. Labor is best induced by dilatation of the os with Barnes' bags. When dilatation is secured, bi-manual version may be done, or if the presentation is marginal or lateral, the membranes ruptured, and nature, perhaps, assisted by the forceps, left to complete the delivery. With Murphy and Wilson we may give ergot freely after the os is dilated. When called during a hemorrhage the tampon should be used till a consultation decides upon the induction of labor, or if the hemorrhage is severe we may proceed at once with bi-manual version, sufficient dilatation being present to introduce one or two fingers. The only period at which this method may be questioned is before the viability of the child. The results are as follows: Hecker, of 40 women lost but 3, while his general mortality was 10 per cent.; Hoffman, in 33 cases lost 2; Spiegelberg, in 74 cases lost 4, or 5 five per cent., while his general mortality was 16 per cent.; Murphy lost no mothers.[1]

Bi-manual Version; the method of Braxton Hicks.—In 1860, Braxton Hicks[2] read a paper before the London Obstetrical Society on a new method of turning the bi-manual, especially as applied to placenta previa, and reported six cases thus treated. The method was suggested to him by the success of Wigand and his followers in performing version by external manipulations. In the cases reported he turned by the bi-manual method as soon as he could introduce one or two fingers through the os, pulled down a leg as a tampon, and waited. I quote the following from his paper: "I have in all cases narrowly watched for any external or internal hemorrhage without having met with it. * * * Turn, and the danger is over if you employ the child as a plug; wait then for the pains, and let nature, gently

assisted, complete the delivery."[1] There can be no question that much of the success of Barnes and Murphy has been achieved through the use of this method, for both employ it when they turn. But in Germany it has found its strongest exponents. Hofmeier first tried it. He had 37 cases, with one maternal death. Behm, encouraged by Hofmeier's success, employed it in 40 cases, and all recovered. Then Lomer had 16 cases with no deaths—93 cases, 1 death, 1 per cent. Eight other assistants had 85 cases, 7 deaths. Total, 178 cases, 8 deaths —4.5 per cent. mortality.[2] No other method has yielded such results in so large a number of cases. The only objection to be urged against the method is the theoretical one that turning increases the fetal mortality, but the results disprove this, for the fetal mortality was 60 per cent.,[3] which is not above the average. The 178 cases were all treated by bi-manual version. If 58 additional cases, in which various other measures had been used before version was employed are included, the mortality was 21—under 10 per cent. This is an additional argument for Hicks' method. In these cases the Hicks' method was used *in toto*, and chloroform was freely administered.

Murphy's Method.—Murphy operates by no exclusive plan, but makes judicious use of several. He is a strong advocate of the induction of premature labor in all cases of placenta previa after the seventh month and "before that period when the hemorrhage is severe, continuous or frequently recurring." His method may be briefly described as follows: 1. Separate the placenta after the manner of Barnes. 2. Dilate the os with Barnes' dilators. 3. If hemorrhage continues, separate the placenta further. 4. When full dilatation is secured, give ergot freely. 5. "If the placenta is marginal or lateral, and the pains fairly strong, I rupture the membranes and leave the course to nature; or, if the head is well into the pelvis, I may apply the forceps; but in the great majority of cases I perform version, preferably by the combined method, and deliver the child as quickly as is consistent with the safety of the mother." The forceps were applied twice. Murphy had 23 cases, lost no mothers, and 13 children—56 per cent.[4]

Finally, we believe that the study of the literature of placenta previa justifies the following conclusions:

(*a*) *What should not be done in treating placenta previa:*

1. *Accouchement forcé* should be absolutely condemned. Lacerations of the maternal soft parts are almost inevitable; perhaps, also, death from shock or *post-partum* hemorrhage. The infant's prospects are not improved.

2. The membranes should not be ruptured before dilatation of the os, except as a step in combined version. Perhaps the greater mortality of Barnes over that of Murphy is due to this difference in practice. The manœuvre frequently fails to arrest hemorrhage; and renders subsequent version more difficult.

3. The tampon should not be used as an exclusive method of treatment. "It is a dangerous thing" (Lomer). It should be used only to gain time for more efficient measures.

4. Ergot should not be administered before full dilatation of the os is secured. It is then of value to hasten delivery and prevent *post-partum* hemorrhage. (Murphy, Wilson.)

5. Complete detachment of the placenta should not be practiced. It is very fatal for the child, and improves but little the prospects of the mother.

6. The fetus should never be turned by internal podalic version, unless the method of combined version has failed. The danger of introducing the hand within the uterus (laceration, sepsis) is thus avoided. Moreover, much time is saved.

7. The forceps should not be used, unless the head is well in the cavity of the pelvis, and hemorrhage or *inertia uteri* is present.

(*b*) *What should be done in treating placenta previa:*

1. In all cases premature labor should be induced after the seventh month, and before that period if the hemorrhage is severe, continuous or frequently recurring. This is done in the interest of both mother and child. The os should be dilated by Barnes' bags.

2. In cases of vertex presentation, when the placenta is marginal or lateral, after dilatation is secured by Barnes' bags (with or without partial separation of the placenta), the membranes may be ruptured, and the course left to nature. In some of these cases the forceps will be needed subsequently.

3. Almost all cases of complete and partial placenta previa are best treated by combined version, with slow and gentle extraction. Version may be done "as soon as one or two fingers can be inserted through the os" (the method of Braxton Hicks), or after

[3] Lomer, *l. c.*, p. 1247.
[4] Murphy, *Medical Press and Circular*, 1885, Vol. II, p. 208.

the os has been dilated by Barnes' bags, and the placenta partially detached (the method of Murphy). Theoretically, Murphy's method allows of quicker extraction. By either, a maternal mortality of less than five per cent. may be expected.

4. Ergot should be used toward the end of labor to insure firm uterine contraction and retraction.

5. Strict asepsis should be maintained.

THE MANAGEMENT OF THE NEW-BORN CHILD.[1]

BY J. J. CONNER, M.D.,
PANA, ILLINOIS.

The management of the new-born child is a subject which, though simple in name, I have found to be laden with very great responsibility. Physicians and parents alike are not apt to stop to consider the dictum of Jefferson's old professor of obstetrics, who was wont to say: "A child that is born does not surely belong to its parents until it has reached its sixth year; it seems to me that such a child is but a loan, on condition of becoming property, provided it be wisely and safely conducted up to the sixth year of its age, for one-half of the annual product of child-birth perishes in six years." In Chicago for the year 1887, forty-nine and one-third per cent. of the deaths occurred during the first five years of life. "It cannot be that this amazing mortality is an inevitable concomitant of the state of existence, but it must be largely a result of ignorance and carelessness as to the hygienic conduct of the neonatus and young child. It is true that a multitude of children are brought into the world with such feeble constitutions or such hereditary depravity as to render protracted existence and maturity impossible; but the population would find an immense augmentation were a sound discretion to preside over the hygienic management of newly-born children." The question may be very properly asked, when should this management begin? I answer, it should begin just as soon as the head emerges from the vulva.

The head of the child should be supported so that the face may be raised up from the bed high enough to prevent the child, in its first gasp for breath, from drawing up mucus, blood, water or fæces into its mouth, and thence into the air passages. If such an accident should occur, the child ought to be wrapped in a flannel blanket and laid on its back upon a table, with its head hanging low down over the edge of the table, and a coarse-grained towel or a piece of mosquito-netting spread over the mouth and face of the child. While one hand is held tightly over the child's epigastrium, the physician should blow steadily and moderately hard through the meshes of the cloth into the child's mouth. Some of the air blown into the child's mouth enters the stomach in spite of the hand resting upon it, some enters the lungs and a part returns back through the nostrils, bringing with it portions of mucus or other foreign matter, which may be dislodged by the idle hand. I am in the habit, especially if the child rallies, of administering a teaspoonful or two of water, either warm or cold, as is most handy, to wash away any phlegm that may be in the mouth or pharynx of the child. It serves a double purpose, for it generally soon acts as a laxative to the young child.

If the child be born asphyxiated, I try to excite respiration as soon as possible by first placing my hand under the back of the child and gently raising the thorax, and shaking it until I find that insufficient. Then I dash a little cold water upon the child's chest and into its face, continuing the raising, lowering and shaking, and also making alternate pressure and relaxation upon the thorax. If these measures fail, I sever the cord, plunge the child boldly into a warm bath, and continue still to imitate respiration by the Sylvester method. One should not be easily discouraged if he fails to readily excite respiration in the new-born child. One person should be detailed for this purpose and instructed to persevere for several hours in his efforts to procure respiration. I suppose it has been the lot of nearly every one engaged extensively in the practice of obstetrics to see new-born children come to life, breathe, feebly though it may be at first, gradually gain strength, and live, when they had been at first given up to death. It has been said that a new-born child has been resuscitated as late as twelve hours after birth. Holding the child up by the feet and shaking it with its head down, has, it is said, resuscitated it after everything else had failed.

In ligating the umbilical cord I prefer a piece of stout tape, about one-quarter or one-third of an inch broad, to any other material. I use two ligatures; one is put on three or four inches from the navel, and the other about five or six inches from the navel. The cord is then cut with scissors between the two knots. I strip the cord completely of all the gelatin of Wharton before I tie either knot. If the cord is well stripped before it

[1] Read at the Annual Meeting of the District Medical Society of Central Illinois, April 24, 1888.

is tied, it dries up much better and is very much less liable to lead to inflammation of the navel.

The cord and navel are dressed with simple absorbent cotton alone. No grease of any kind is allowed to be put on them. If grease be put upon the navel it will be apt to turn rancid and produce irritation, and possibly lead to inflammation, erysipelas, and umbilical hemorrhage. It is thought by some that an inflamed navel often produces trismus nascentium by reflex irritation and systemic blood-poisoning through absorption of pus, etc., from the neighborhood of the umbilicus. Before putting the child's clothing on, it is thoroughly greased from the head to the feet, preferably with common lard. Special attention is given to the armpits, groins and other creases of the skin. Nothing will clean a child so readily of the vernix caseosa as good fresh lard. I do not allow any soap to be used upon the tender skin of the new-born babe. The face, hands and buttocks, if soiled by fæces, are gently and very lightly washed with a little soft water, into which the yolk of an egg has been thoroughly beaten up.

As the new-born child has the power of generating body-heat but very feebly, it should be dressed in material that will not conduct animal heat away from the body. That material of course should be woolen. I like the very softest and downiest flannel. There should not be a particle of starched goods in the make-up of the child's toilet. The clothes should be made up loose and baggy, somewhat after the style of the "Mother Hubbard" dress. It is not necessary to put on a belly-band if the child's petticoat has a waist-band attached to it. If there is no waist-band I put on a belly-band. It prevents the dressing of the cord from slipping around and getting misplaced or entangled in the clutches of an awkward nurse, and hence is not so apt to be suddenly jerked off of the child's belly or otherwise injured. I think it prevents hernia too, especially in children prematurely born or otherwise undeveloped. A good flannel bandage will go a great ways in preventing colic in the new-born by keeping the belly warm. The best material of which to make a belly-band is an old piece of woolen shawl, cut bias, so as to give elasticity and allow the belly to enlarge as the bowels evolve the intestinal gases through the process of digestion.

For the constipation so often met with in practice with babies, I have come to rely almost exclusively upon the compound licorice powder of the Pharmacopœia. A suppository of soap generally answers every purpose, and soap is found in every household. An elegant mixture is composed of equal parts of castor-oil and glycerine, to which a drop or two of oil of peppermint has been added. By correcting the mother's habit of costiveness it will generally suffice also for curing the habit in the child if it nurses, as all babies ought to nurse their own mothers.

I believe a child should have a full bath every morning of its life the first year of its existence. It should be entirely undressed and made to sit, or laid down, in a bath-tub. Its entire body should be thoroughly washed and rubbed with the palm of the hand. It should then be suckled and again put to bed, where, if it be a healthy child, it will sleep several hours.

I have no doubt that all practitioners will admit that the most difficult thing in the management of the new-born child is the proper feeding of it. It requires very great judgment on the part of the physician to at all times select the proper kind and amount of food which a child requires. It requires great tact and perseverance on his part to see that the mother and nurse faithfully carry out his instructions. A great many mothers are wofully careless and negligent in this important matter; others are ignorant to an alarming degree, and fail to comprehend the most plain and common-place instructions. Some are lazy and almost criminally wilful, and determined not to carry out the instructions left for them. It is needless to say that without a perfect coöperation of physician and nurse, or mother, that but very little indeed can be accomplished; but with a combination of interest by mother, nurse and physician wonders are accomplished.

If the baby has to be fed or raised by hand, the first thing to secure is a proper feeding-bottle. The shape of the bottle itself is to be looked after. A bottle with angles to it, like a common prescription vial, is to be avoided, for it is hard to clean, and a nurse who is slovenly, careless, or in a hurry to stop a crying baby's mouth, will often give a child milk which is contaminated with decomposing materials which are found sticking to the angles of the bottle at its bottom and neck. There is a feeding-flask now upon the market known as the "Graduated Nursing Bottle," and was made at the suggestion of Prof. Louis Starr, of Philadelphia. It is made of transparent flint glass, thus showing plainly the slightest foulness at a glance. The interior surface is made entirely free from angles, and an accurately graduated scale of fluid ounces, and half ounces or tablespoonfuls, is blown in

the glass. This bottle will be found very convenient and easily cleaned, and accurate in measurement, thus combining the essentials of a feeding-bottle.

The nipple for the bottle should be of the best black rubber, so that it will not irritate and make sore the child's mouth. I prefer the milk from a cow which has recently calved to that from a cow whose calf is some months old, or to that from what is commonly called a "stripper." The freshly calved cow's milk is richer in oil globules and more easily digested by the young child than the milk from a cow which has been milked for a long time since calving. The milk from a stripper has more casein in it than that of the newly calved cow, and is consequently apter to curdle into large cheesy masses and give rise to colic, indigestion and diarrhœa. The formula which I have found to correspond best with the mother's milk, is about the following, viz.: Take one part of rich, new cream from the top of the milk-pan and add another pint of fresh milk and two pints of pure water unboiled; sweeten with milk-sugar preferably, but pure granulated sugar answers fairly well and is found now in every house; the whole should be slightly salted and warmed to about 100° F. A child during the first month of its life, should be fed about once in two or three hours during the day, and once in four or five hours during the night. Be careful about over-feeding the baby. Few children die of starvation in this land of plenty. They are nearly all over-fed with cow's milk, which brings about impairment of the gastro-intestinal functions. I have seen children literally starve to death after they had been over-fed to such an extent that they were unable to digest, assimilate and absorb nutriment which they were given. In just such cases as the ones now mentioned, we may be able to rescue a starving babe by the judicious application of cod-liver oil and mere common lard to the body of the child. One half ounce of cod-liver oil well-rubbed into the skin once every four hours, will often save the child, when otherwise it will surely die. The skin of a young child is very porous and will absorb nutriment rapidly. The stomach and bowels should be let alone for awhile during the rubbing in of the oils. I admit that it requires great perseverance and almost blind faith to succeed, yet success will sometimes be achieved where the usual method fails. Those of my colleagues who have never tried this method of feeding may have grave doubts of its efficiency, but I will only call to their mind the readiness with which a great many medicaments are taken up by the skin and appropriated, and I ask why not nutriment as well? Before entirely condemning the method, I bespeak for it a fair trial at your hands. Of course medicines of various kinds may be very appropriately combined with the food substances and administered together. The secret of success of this method I believe to lie in the property of osmosis of the skin, and the small amount of nourishment required to sustain and strengthen a famishing child. After the alimentary canal has had a rest, the digestive organs will then resume their proper functions. All we have to do is to keep the child alive for awhile, thereby bridging over the stream, and we shall have gained our reward. Shall we give small children alcohol? I very emphatically say yes. Why? Because I verily believe it to be a food as well as a powerful, and at times the best, stimulant known to medical science, when used in certain imperative conditions.

PTERYGIUM COMPLETELY COVERING THE CORNEA.

BY JULIAN J. CHISOLM, M. D.,

PROFESSOR OF EYE AND EAR DISEASES IN THE UNIVERSITY OF MARYLAND, AND SURGEON-IN-CHIEF OF THE PRESBYTERIAN EYE AND EAR CHARITY HOSPITAL OF BALTIMORE.

So seldom is a pterygium seen to exceed in its growth the border of the pupil, that some ophthalmic surgeons of large experience have never seen one of more extensive growth, and have consequently written that a pterygium can never shut out sight by covering the cornea, unless one starts from each canthus, and after many years of growth they meet half way over the pupillary area. The fallacy of this opinion I have an opportunity of showing every now and then, and more particularly in the last week. In accordance with professional experiences, three of these unusual cases presented themselves for treatment during one week at the Presbyterian Eye and Ear Charity Hospital of Baltimore.

Case I.—J. M., a man, 72 years old, had a pterygium on each eye, growing from the inner canthus. He had been more or less annoyed with them for twenty-five years. In the left eye the growth, quite a thick one, was encroaching upon the pupillary area and had commenced to interfere seriously with his vision. In the right eye the pterygium in its continuous development had not only completely covered the pupil, but was nearly touching the external corneal margin, so that nearly the whole cornea was covered over by the flesh-like layer. The external

canthus was perfectly free of all conjunctival complications.

Case II.—M. S., a woman, 68 years old, had the growth only on the right eye, and said that it was of two years' duration. She was not intelligent, and I could not get from her whether it had made her blind for that length of time or not. Evidently the starting point of the pterygium from the inner canthus was of much longer duration. In her case the web was a broad one, completely concealing the pupil, and extending half way from the external border of the pupil to the external border of the cornea. There was no growth from the external canthus, and the left eye was entirely free.

Case III.—J. S., a man, 63 years old. In this case the right eye alone was involved. The pterygium was of twenty years' growth. Starting from the common site, the inner canthus, it had slowly encroached upon the pupillary area, and had finally shut it in, in its continuous progress toward the external surface of the eye. The pupil could be seen only by looking very obliquely through the small rim of clear cornea on the side of the external canthus.

It was the presentation of these three cases for treatment on nearly consecutive days that attracted especial notice, and induced me to report them.

Society Reports.

AMERICAN MEDICAL ASSOCIATION: SECTION WORK.

First Day, May 8, 1888.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

The meeting was opened by the President, Dr. Ely de Warker, of Syracuse, N. Y., who welcomed the members to the present session, and delivered his address on the subject

How Gynecology is Taught,

in which he discussed the various methods of instruction, and concluded by paying a glowing tribute to American gynecology, and especially to its founder, Marion Sims.

Dr. Price, of Philadelphia, next followed with a paper on

Free Nursing as Organized in Philadelphia.

He described the system which had been there adopted of furnishing the poor and indigent with skilled nurses, by which operators were enabled to perform even most difficult operations in the homes of the poor, with proper assistance.

This institution was organized two years ago by two charitable ladies of Philadelphia. It is supported by voluntary contributions and such small amounts as the patients are able to contribute. The corps consists of seven well-trained nurses and their assistants. Two maternity nurses attend to the obstetrical part of the work, and separate nurses are employed for the care and attendance of contagious diseases. When an operation is contemplated at the home of the poor the proper nurse at once makes all necessary preparations and everything is brought in readiness for the operation. By this means the worst hovels in the very slums of society are quickly cleaned and made comfortable, so that even abdominal sections can be performed with safety.

This excellent plan is shown by the astonishing result of only *one* death in over ninety abdominal sections. The immense work done is further shown that out of 361 general gynecological cases, 90 were of a surgical character. In this year alone over two hundred cases were attended.

Dr. W. W. Jaggard, of Chicago, next followed with the reading of an essay, entitled

The Relation of Endometritis Gravidarum to the Persistent Vomiting of Pregnancy,

in which he included the report of a case of hyperemesis gravidarum caused by endometritis.

In the case reported abortion was induced by introducing a bougie between the uterine walls and membranes after all other means for arresting vomiting had proven futile. Eight hours later the ovum came away and the placenta was removed according to Credé's method. The fetus was of eight months' gestation. The abortion was immediately followed by cessation of the vomiting. That the vomiting was not due to an artificial displacement of the uterus was proven by the fact that it occurred as late as the sixteenth to the eighteenth week.

Dr. Adams Allen, of Chicago, said he accepted the case reported as a type of cases not infrequently met with it. He arose more particularly, however, to emphasize the method of treating uncontrollable vomiting generally. Most authorities recommend temporarizing and delaying an interruption of pregnancy. The speaker thought such delay proved, too frequently, disastrous. The case reported showed the necessity of departing from such a rule, because a higher value should be placed upon the life of the mother than the child. The speaker now did not hesitate to induce abortion at an earlier

period than formerly, believing that thereby he could save life which otherwise might be destroyed. He therefore thought the essayist was perfectly justified in his treatment.

Dr. W. H. Wathen, of Louisville, was particularly interested in the subject of pernicious vomiting in general. He had seen but one case of truly uncontrollable vomiting, in the practice of another physician. The patient was two or three months' pregnant, and could retain absolutely nothing on her stomach, not even a tablespoonful of cold water. She was thoroughly emaciated.

The speaker at once dilated the cervix to the depth of one inch and a half by means of a steel dilator, not for the purpose of inducing abortion, but as a means of arresting the vomiting. Dilatation had previously been practiced by the attendant with sponge tents without affording any relief. After the dilatation, as aboved described, the nausea and vomiting abated, but abortion occurred a few days later. Unfortunately, the patient died of septicæmia sometime later because the attending physician could not remove the placenta entire and left portions of it attached to the uterus. Had the speaker attended the case throughout, he would have removed the placenta by the curette, if necessary. Although dilatation in this case was followed by abortion, it is not always so followed, and in these cases it relieves vomiting as well.

Dr. Nelson, of Chicago, gave his experience in cases in which vomiting is due to flexion, either of the uterus primarily, or due to the displacement of the ovaries or disease of the adnexa.

In one case, a complicating fibroid tumor was the cause of the flexion, and hence also of the vomiting. He would relate a peculiar experience in connection with this matter. He once attempted to introduce a No. 12 English catheter for the purpose of inducing abortion. He allowed it to remain in situ a few minutes and then withdrew it with the stilet. After withdrawal he noticed a white, milky fluid, about twenty minims in amount, exuding from the end of the catheter. He was greatly puzzled to account for it. Had he opened an abscess cavity, or was it some physiological secretion—perhaps the so-called placenta milk? In his consternation, he neglected to save the fluid for examination, and it was therefore lost. It was possible that he had not exerted sufficient force to rupture a blood-vessel, but that the end of the catheter nevertheless passed into one of the uterine sinuses. The patient made an excellent recovery. The speaker believed that the fluid extracted was normal to this body. He requested his hearers to make similar observations if possible and report them to him if they have similar experience.

Dr. Maury, of Tennessee, thought we should always endeavor, if possible, to preserve the fetus, but if the question of the safety of the mother's life arises we should not hesitate to induce abortion. He thus induced abortion three times according to the method reported by Dr. Jaggard.

Dr. Pollard, of New York, suggested the following modification: Instead of introducing a flexible bougie, a harmless and serviceable method is to take a large-sized piece of catgut, double it on itself, thus introduce it into the womb and leave it there. The catgut should first, however, be rendered aseptic. He resorted to this method in an extreme case with perfect satisfaction and good result.

Dr. Morse was of the opinion that in the great majority of cases, abortion results spontaneously, hence the induction of abortion will not be necessary.

The speaker reported two cases. In one the vomiting had lasted three months. After stomach feeding had become impossible, rectal alimentation was resorted to with some success for two or three weeks. Finally, however, it became necessary to induce abortion, which, unfortunately, resulted fatally.

The patient had had a chronic endometritis before marriage. An examination after marriage showed that the disease still continued, but on account of the absence of any great inconvenience the patient declined further treatment.

She then became pregnant and the result was the setting in of excessive vomiting. Abortion was produced by means of the introduction of a sound and tamponing of the upper part of the vagina. The ovum came away in about five hours. As the placenta did not come away entire the uterus was curetted thoroughly. The nausea and vomiting were indeed arrested, but the patient died of heart-clot the next day. The speaker thought that too long a time had been allowed to elapse between the discharge of the ovum and the removal of the placenta. If the uterus had been curetted immediately she would probably not have died. Another similar case reported terminated in recovery.

Dr. Marcy inquired into the relationship of the placental and uterine villi to each other in the case reported by Dr. Jaggard. The speaker was of the opinion that there was a lack of proper relationship of the villi of absorption to those of secretion. At first the development of these sinuses is glandular,

but afterwards another process takes place, and this change is the real cause of the resulting endometritis. It is not really an endometritis—an inflammatory process—but a lack of proper development. He believed Ercolain was correct in his teachings regarding the structure and functions of the utricular glands. In the majority of cases the speaker thought dilatation for the purpose of arresting vomiting was useless, because it produced either death of the fetus or resulted in abortion in consequence.

Dr. Jaggard, in concluding the discussion, entered a word of protest against dilatation of the cervix simply as a means of arresting vomiting. In the largest number of cases it terminates in the premature expulsion of the ovum. He also preferred the introduction of a solid flexible bougie to a catheter with mandrin, on account of the danger of introducing air or septic material into the cavity of the womb.

Dr. Goodell, of Philadelphia, next read an entertaining, and in part humorous, paper on the

Nervous Rectum.

He described the rectum as being sometimes insane, as it were, whilst the rest of the body enjoys perfect sanity. One variety of this neurosis is the hysterical rectum, the muscles being thus affected, but the sphincters more so than the other set of muscles. A frequent form is spasm of sphincter, which renders defecation painful, and hence induces costiveness. These victims become easily addicted to opium eating. When the rectum is loaded a pulsating pain is felt. If there be in addition some ovarian irritation and enlargement the affection becomes very distressing.

Another form the speaker alluded to as the "jealous" rectum. He gave some very ludicrous instances where the rectum put its veto on any attempts at indulging in social intercourse. One lady always began to have an evacuation from the bowels as soon as she received a letter from her husband, and was obliged to delay reading it until the rectal demands had been satisfied. A second individual would soil her bed after any violent mental emotion. All these persons were kept prisoners at home and had to abandon social intercourse.

A third form he described as "follicular colitis" or "membranous enteritis." He found this affection so often in hysterical patients that he looked upon it as a neurosis, just as pruritus, shingles, etc., are nervous skin affections. He found all these forms of rectal trouble as being peculiar to emotional women of high intelligence: none of them belonged to the lower walks of life. The diagnosis between these neurotic troubles of the rectum and disease of the coccyx is readily made by the introduction of the index finger into the rectum and the thumb over the coccyx, showing that this appendage is movable.

The treatment depends on the form of the trouble. He regarded that of Weir Mitchell for nervous prostration as the best. Seclusion, forced feeding, massage and electricity, the latter two equalizing the nervous fluid and stimulating a healthy action of the nerves. As soon as enemata can be borne, they should be administered before bedtime. Suppositories of iodoform act beneficially, and, in case of spasm of the sphincter, stretching of the sphincter ani. Follicular colitis is almost incurable, but may be soothed by means of suppositories of iodoform, antipyrin, etc. Sometimes injections of lime water or Carron oil greatly relieve this trouble. He cautioned strictly against the use of opium in any form, as these patients are very apt to become opium eaters. Altogether the best medication consists in the administration of remedies constitutional in their action. His favorite prescription is the pil. sumbul comp.; Blaud's pill is an excellent remedy, beginning with one pill three times a day, gradually increased until three are taken after each meal. Occasionally he gave as many as five after each meal. Pills composed of the three valerianates (zinc, iron and quinine) are of great value, also pills composed of chloride of gold and soda. When malaria is at the bottom of the trouble, Fowler's solution acts well. The bromides are often needed and may be advantageously combined with the bitter tonics, as the tincture of gentian comp. When the paroxysms are sudden, antipyrine and the hydrobromate of hyoscine are serviceable. Absolute rest of mind and body secured by absolute seclusion in a darkened room is sometimes indispensable.

Specimens and Instruments.

The Secretary, Dr. E. W. Cushing, presented for Dr. Reamy two specimens of tubercular salpingitis, the tubes and ovaries having just been removed by Dr. Reamy.

Dr. Howard A. Kelly, of Philadelphia, next exhibited a number of gynecological appliances for the use of the specialists in this department. A number of rubber sheets of various shapes to adapt this for the different operations, ovariotomy, perineorrhaphy, etc., were shown, their object being to drain off the fluids thoroughly and yet insure cleanliness. An ingenious rubber bed pan was

also shown. A pair of simple leg holders (*Beinhalter*), inexpensive and easily made, were passed around. Among instruments devised by the same gentleman were a speculum for the knee-chest position, a series of glass (antiseptic) catheters, drainage-tubes with flanges, new sponge forceps, knife-blade tenaculum, a modification of the Bozeman-Fritsch catheter, etc.

Cases of Hysterectomy.

Dr. Gordon then gave a brief account of three cases of vaginal hysterectomies, lately performed. He made an earnest plea for an early operation, as it is now assumed that cancer is first local and afterward constitutional. It should be a golden rule, that where a disease has naturally a fatal tendency if left to itself, an operation is justifiable even if it should terminate in death. The immediate mortality in hysterectomy is not very great; Martin reported only eleven deaths after sixty-six operations.

His first patient was 38 years of age; the evidence of cancer was only of six weeks' duration, according to symptoms, consisting of a growth on the posterior lip of the cervix. Vaginal hysterectomy was performed, with complete recovery. In another patient, 56 years of age, who had an offensive discharge and hemorrhages, the operation was followed by immediate recovery. In a third case, where the cancer was of a year and a half's duration, the patient died from supposed inflammatory intestinal obstruction.

Dr. Marcy reported three cases in which Martin had operated in Boston. One of these subsequently died from hemorrhage, the autopsy revealing that one artery had escaped ligature. He could hardly account for this when noticing Martin's thorough method of securing the blood-vessels. Another case died from heart trouble. An autopsy was refused.

Dr. Goodell was still on the fence. He operated twice in this manner; his first patient died of septicæmia on the third day. The second recovered from the operation, but died from hemorrhage in less than six months. In the future he would leave the clamp forceps on the vessels instead of ligating them. In liberating the uterus from its attachments, he first made the posterior incision and hooked down the organ by means of the old obstetric crochet. He thought that in the future, however, he would make no attempt to retrovert the womb, but simply draw it down with the forceps attached to permit drainage.

Dr. Cushing, of Boston, described Martin's method: He hooks down the uterus with a powerful forceps. Alluding to the paper of Dr. Reeves Jackson, at the last International Medical Congress, the speaker said he laid great stress upon the statistics on the period of time a woman lived when not operated on. The speaker would reply as did Dirner, of Buda-Pesth, that five years longer life of misery in one woman does not count against another whose life is greatly improved by operation.

Dr. Goodell said he had had excellent results from the high vaginal amputation—one patient lived fifteen years after this operation had been done, and the stump treated with a mixture of 15 grains of the bichloride to an ounce of collodion.

Dr. Gordon said in reply, that if the whole uterus is out, this is better than having only part of it out. He retroverted the uterus by means of a stiff sound.

SECTION ON DISEASES OF CHILDREN.

Dr. Charles Warrington Earle, of Chicago, read a paper on

Infant Feeding:

(1) Foods for Prematurely Born Children; (2) Mixed Diet; (3) Artificial Foods; (4) Feeding in Acute Disease.

Dr. Earle began by saying it was particularly appropriate to present to the section a brief *résumé* of what Baginsky, the latest German author on diseases of children, writes on the subject.

The greatest mortality in all climes and among all nations is due to the lack of mother's milk. In Berlin, one-half of all children born out of wedlock die within six months, and during the summer months a large proportion of children succumb to errors of diet.

Fermentation of milk occurs only in consequence of the introduction into it of micro-organisms. If the milk be received by a sterilized tube into a sterilized receptacle directly from the udder of the cow, it will not ferment, nor become acid, though kept indefinitely. But except these precautions are taken, the germs always gain access to it; consequently in order to prevent its fermentation, it is necessary to heat it. It can be sterilized by heating to 70 degrees for an hour, by which process the adult bacilli are killed; although it is necessary to repeat the process for an hour each day for four or five days in order to kill the spores. Heating to 100 degrees by a current of steam for one hour will sterilize it completely, but boiling coagulates the

albumen and to some extent changes the milk sugar.

The first process in the fermentation of milk is due to the action of a bacillus, and consists in the conversion of the milk sugar into lactic acid. This process ceases after a small quantity of acid is formed, but if the acid be neutralized by chalk the fermentation will go on until the milk sugar is all decomposed. By the change of re-action of the milk the casein is coagulated. This coagulation is said to be due to the action of the acid and not directly to that of the bacillus. When the milk sugar is converted into lactic acid, another bacillus—bacillus subtilis—attacks the lactic acid and converts it into butyric acid with evolution of carbon dioxide and free hydrogen. This bacillus cannot act on milk sugar unless it is first converted into lactic acid.

Under exceptional circumstances there is formed in milk a substance first discovered by Prof. Vaughan of Ann Harbor, and named by him "tyrotoxicon" (cheese poison). This substance is a crystalline nitrogenous substance, and is supposed to be a ptomaine. When taken, it produces pain at the base of the brain, vomiting or retching, and purging. When given to an animal, similar symptoms are produced. Prof. Vaughan believes this to be the cause of cholera infantum. Tyrotoxicon is formed spontaneously in milk after some months; but it will be produced very quickly if some milk in which it has been formed be added to fresh milk. Its formation seems to be connected with the butyric acid fermentation.

In conclusion, Dr. Earle asserted that nature does not afford, nor can art supply, a substitute for mother's milk. Mothers should be encouraged by every argument possible to nurse their children, and the dangers of too early weaning should be demonstrated to them. If from causes which we cannot control, and which seem rational and valid, a mother cannot nurse her child, then in cities at least, a wet nurse should be procured. A mixed diet is preferable to an artificial one. For very young infants, in lieu of mother's or nurse's milk, cream with barley, rice or oatmeal water, to which milk, sugar and either common salt, phosphate of lime, or lime water, in small quantities, is added, seem to agree best. For older children, cow's milk and the so-called milk foods, are best. It would seem from some recent analyses of cow's milk that if all kinds of fermentation can be prevented, without the task of preparing cow's milk, so that it will agree with infants, feeding will not be as difficult as it has formerly been. It also seems that it is along this line that investigation in the future should be made. We must not only insist that good milk shall be provided, but also that it shall not have in it bacteria. If milk is used, let it be thoroughly boiled, and for a long time. If it is diluted with water, let the water be absolutely pure. If the attempt is made to make it more nutritious by the addition of cream, let it be that which has not already undergone partial decomposition. The sugar added should be pure milk sugar, and if a small amount of wheat and flour should be used, this too should be thoroughly cooked. If artificial foods are used, let the clinical test decide which shall be selected, and when food is found to agree with a child, let the growth and increased nutrition of that child, or its loss in weight and commencing atrophy, be the guide for the substitution of some other food. I cannot designate particular foods for reasons perfectly obvious. Every food has its advocates. Every food has its chemical analyses, which prove without a shadow of doubt that it is chemically and physiologically the only substitute for mother's milk, and yet every one of them sometimes fail us. I will admit that this is true of mother's milk in rare cases, but as a rule let our advice be in the order I now name: Mother's milk, nurse's milk, mixed diet, cream foods, milk foods, malted foods, farinaceous foods, always pure; free from bacteria, and each preparation, whatever it be, frequently inspected.

SECTION ON DERMATOLOGY AND SYPHILOGRAPHY.

The session was opened by an elaborate and exceedingly interesting paper by the Chairman, Dr. Bulkley, on

Syphilis as a Non-venereal Disease.

The discussion on the

"Etiology and Treatment of Eczema"

was opened by Dr. Bulkley, who said:

The question presented for our discussion this afternoon is one of such magnitude that it is manifest that not more than the outlines for consideration can be sketched at present. In the etiology of the disease we have to distinguish between the predisposing and the exciting causes of eczema, between the constitutional state or condition, and the special determining causes of the attack, internal and local. We know as yet nothing of the real internal causation of eczema, except as we can observe clinical facts of the association of certain symptoms or conditions of system in connection with, and apparently

causative of the disease. I believe the first element to be recognized is *debility* in some form or other. Eczema never occurs except as an evidence of lowered vitality, either general or local. The local element will be considered later in connection with the local exciting causes of the eruption.

The evidences of debility in patients with eczema take three general forms: First, those which relate to digestive and excretive functions; second, those which effect the nervous system and present neurotic symptoms; and, third, those connected with nutrition, or the life process of the body, known as the scrofulous or strumous state.

The first of these is by far the most common, forming fully one-half of all cases, and represents what is known as gouty eczema; the second, or nervous causes, may exist alone in a certain proportion of cases, but often enters as an element in patients belonging to the first class; the third, or strumous condition, is less common than the others, and rarely determines the disease alone, without the intervention of the two preceding causes.

This lowered vitality may come from many causes. In some instances simple over-work or worry, producing nervous exhaustion, may induce and keep up the disease. In more cases assimilative debility, manifested by disorders of the digestion and excretions, plays the most important part, while in other instances a strumous condition of the system seems to be the main factor, and in a few instances heredity is an important element.

Digestive derangements are undoubtedly the most important elements to be considered etiologically in eczema, and again and again their effect may be observed by careful study in many cases. Acidity will always aggravate an eruption of eczema of any extent, and constipation will often be followed by fresh outbursts of the same.

Dr. Zeisler, of Chicago, said: there are two theories concerning eczema: The first, advanced by Hebra, that eczema came from local causes. His strong argument in favor of this theory was that he could produce a local eczema in any individual, in any place, and at any time. His successful treatment lent weight to this theory. The second theory, held extensively in England and America, represents eczema as a constitutional disease, due to ill nutrition. The truth probably lies between these two theories. Many cases are no doubt due to local causes, *e. g.*, eczemas of washerwomen, shoemakers, surgeons, exposure to sunlight, etc. These may, however, be explained by individual peculiarities. Many cases are undoubtedly due to internal causes, but to ascribe all cases to constitutional causes is to transcend our knowledge. Eczema in children is sometimes due to nervous causes, as in teething. Rheumatism is a cause of chronic eczema. Disturbances of digestion are too often blamed as the cause of eczema, for the number of cases of indigestion is out of proportion to the number of cases of eczema, except in infancy. Whether eczema be due to organisms or not, remains to be seen; if so, many subdivisions of what we now regard as one disease will have to be made. I believe in local treatment, but my views have, of late, been modified. I limit the use of arsenic to chronic, dry eczema.

Dr. Ravogli said: in considering the etiology, it is necessary to look at the general condition of the individual. The same cause often works differently in different individuals. This is due to the general condition of the skin, whether it is soft or tough. Thus we find that age makes a difference. The symptoms in children are entirely different from those in adults. It is more acute in children, and in old age more chronic and inclined to the scaly form. He did not believe in a scrofulous eczema. Eczema is a catarrhal condition of the skin. Scrofulous subjects may, however, be more predisposed to eczema. Obstacles to the circulation, as scars, fractures, and varicose veins, are sometimes a cause of eczema. Had had excellent results with the use of salicylic acid and resorcin in eczema of children.

Dr. Reynolds, of Chicago, said that the causes of eczema were both local and constitutional. He relied most upon the local treatment, never losing sight of the constitutional condition, which may aggravate or prolong the disease. For the local treatment, he divided eczema into acute, sub-acute and chronic cases. The treatment of the first was soothing, of the second, soothing, and mildly stimulating, and of the third stimulating. The other constitutional conditions, of course, require their proper treatment.

Dr. Rickets, of Cincinnati, said that he had seen a number of cases in the city during the late epidemic of typhoid fever, and had invariably found an excess of acid in the urine. What relation there was between this fact and eczema he did not know.

Dr. Fleisher, of New Haven, said that gouty eczema was a new form to him, and that eczema was due to blood-stasis, either venous or arterial. He believed struma a cause. He considered that Hebra's experiments in the production of eczema proved nothing, nor was it established that it was caused by special occupations. Such coinci-

dence might be due entirely to similarity of conditions. In the treatment he had found arsenic of great value, but he uses it less than formerly. He believed in the three-fold division of the disease. He had obtained good results from mild external treatment, especially from the use of the ointment of rose-water. In some cases he found great benefit from free purgation.

The next paper read was by WILLIAM T. CORLETT, M.D., Cleveland, on

A Clinical Study of So-Called Prairie Itch.

From time to time one meets with reports in the medical press of diseases of the skin, closely allied in symptoms to scabies, yet it is claimed differing therefrom in certain essential details. This is claimed to possess four cardinal diagnostic points: The first, pruritus, is always present but varies in intensity, being in some cases continuous, but in some cases there are periods of exacerbation, notably at the close of the day. The second symptom consists in a papillary eruption varying in distribution. The hands and forearms are most frequently affected, next in order the trunk and thighs, while the face does not always escape. The third symptom, or more properly, etiological feature, has been the *bête noire* of several amateur microscopists, who have ascribed its contagious or infectious nature to a hitherto unlabeled parasite. The fourth distinguishing feature arises from the observation that, although resembling scabies, yet it does not yield to therapeutical measures best suited to that disease. One or more of these features are present in every case of so-called prairie itch.

In 1854 Dr. William Brodie, of Detroit, took the position that prairie itch was unrelated to scabies, which position, if I mistake not, he still holds, despite the advance made in dermatology since then. In the winter of 1885, it was estimated that one person in every twenty in Louisville had the itch. This epidemic, Dr. Hyde, of Chicago, thought was probably due to an unusual series of cold waves from the Manitoba region. A writer in the Kansas City *Medical Index* for August, 1886, describes the group of symptoms herein considered, and concludes that it is not scabies, nor a disease peculiar to this country. Dr. Engstad, of Dakota, however, has made a careful microscopical investigation and has not found the acarus.

In November, 1885, the "new itch" was reported to be epidemic in Portage and Wayne counties, Ohio, and a committee was appointed from the Northwestern Medical Society to investigate the same. The committee reported: The disease for the most part is scabies, due to the acarus scabiei. The treatment and hygienic measures suggested by the committee were successful in exterminating the epidemic.

(The doctor here gave a more or less detailed account of the history of ten cases which he had studied in hospital and private practice, and which belonged to the same category as those he was discussing.)

In May, 1887, I saw several cases of what is popularly known as the Michigan itch, or lumberman's itch, in the hospital of the University of Michigan.

Other cases in many Western towns of Pennsylvania, which claimed to be specimens of prairie itch, were found to range from scabies to phtheiriasis, from erythema simplex to eczema pustulosum, from pruritus to herpes, and from pityriasis to xeroderma. It is not that scabies has disappeared with increasing civilization, but that we lose sight of the clinical fact that the acarus scabiei is only a local irritant, inducing in one a papillary, in another a vesicular eruption, which in another again may become pustular. Frequent bathing will put a limit to this local invasion; thus it is seldom seen on the hands and faces of those who bathe frequently. Again, the senso-neuroses, which become apparent to American dermatologists, often baffle the most skillful. But, from the mass of cases examined, it is apparent that there exists no material for a new disease, but an appalling need of a more thorough knowledge of those we already have.

DR. ZEISLER, of Chicago, opened the discussion of Dr. Corlett's paper by saying that the cause of the so-called prairie itch was ignorance in regard to skin diseases. The doctor related several incidents showing the ignorance of many of the general practitioners with regard to dermatology.

DR. REYNOLDS said that his practice in the West had given him opportunities for seeing many cases of this so-called new disease. He had always found that this diagnosis was made by men who were not well posted in dermatology. All the cases of prairie itch he had ever seen were typical cases of eczema. He saw little of scabies, but many cases supposed to be scabies were, in reality, eczema. The peculiarity of the prairie itch is the appearance of contagion, which is thought to distinguish it from eczema. This imaginary contagion may be due to the fact that all of a family are under the same hygienic, dietetic, and local conditions. Itching seems to be almost contagious, and the scratching ensuing may occasion a disease of the skin.

Second Day, May 9.

SECTION ON OBSTETRICS AND GYNECOLOGY.

ELY VAN DE WARKER, President.

E. W. CUSHING, Secretary.

The second day's proceedings opened with the election of Dr. W. H. Wathen as Chairman of this Section.

Dr. A. B. Carpenter, of Cleveland, was next nominated as Secretary, and, as no further nominations were made, was elected by acclamation.

The first paper read was by DR. L. H. DUNNING, of South Bend, Ind., on

Double Uterus and Vagina.

The paper was illustrated by a number of large drawings on the various malformations of the uterus and vagina, consisting in duplicities of these organs. After explaining the origin of these anomalies from errors in development in the generative organs from Müller's ducts during embryonic life, and presenting the various forms of double uterus and vagina, he gave complete statistics of the number of such cases reported up to the present time. When pregnancy occurs in a double uterus the unfavorable position of the impregnated uterus is apt to cause miscarriage or difficult labor. These abnormalities are usually confined to the uterus and vagina, the ovaries being rarely implicated. This is readily explained by the fact that these organs are developed from separate germinal bands. Of great interest are the anomalies of menstruation. In addition to the healthy action of the ovaries, there must be a communication between the tubes and uterus, and of the latter organ with the vaginal outlet, to establish normal menstruation. If, owing to malformations, there be any obstruction, there may result various anomalies. One-half of the uterus may become impregnated whilst menstruation occurs from the other half, or pregnancy may occur in both divisions, with different periods of impregnation. This departure from normal menstruation shows the important influence of the uterus over this function. The effect of a duplex vagina over pregnancy is but little described by text-books. Whilst impregnation may take place, labor may be delayed at either by the presence of this septum. It may become torn through the progress of labor, or must be artificially divided before the latter can be completed. The essayist said it may be incised, or removed by the galvano-cautery. Personally, he favored excision and suturing the edges. If an incision be made, it should be crucial. The time of interference is of some importance; if the anomaly be discovered but shortly after pregnancy it is better to wait until the fourth or fifth month before operative measures are resorted to, as pregnancy is less likely to be interrupted at this time than in the earlier months. At all events it is better to cut the septum than to allow it to be torn away during labor.

Finally, the author came to the following conclusions:

1. Congenital malformation of the uterus or vagina are more frequent than is usually supposed.

2. Of the different anomalies, uterus bicornis is the most frequent form—over fifty per cent.

3. The fecundity of women thus affected is not materially diminished.

4. As a result, however, difficult labors are more numerous.

5. In all established cases of uterus bicornis pregnancy has thus far occurred.

6. The forms of malformation of the uterus in which abortion or miscarriage are most apt to occur are the uterus didelphys and uterus bilocularis.

7. Both divisions may be pregnant at the same time and in different stages.

8. Disorders of menstruation are very apt to occur.

9. The amount of the menstrual fluid when normal is small.

10. Menstruation may occur simultaneously from both uteri, or one may alternate with the other.

11. The disturbances caused by these anomalies shows the important part that the uterus plays during female life.

DR. W. H. TAYLOR, of Cincinnati, in opening the discussion, stated that in the past two years he had seen two cases of duplicity of the uterus and vagina. One was a case of complete separation of the vagina, the septum extending from the osteum vaginæ up to the os internum of the uterus (os bilocularis). This woman became pregnant, and at term the child, in breech presentation, straddled the vagina and tore a portion of the septum away in its descent. The untorn portion had then to be divided. This case occurred in the Cincinnati Hospital. The other case did not become pregnant. Here the partition extended only from the external genitalia to the os (vagina bipartitus). This is a much rarer form of malformation. Courty says a double uterus without double vagina occurs one hundred times, whereas a double vagina without double uterus only fifteen times.

Dr. Goodell reported a case of double uterus in which he had made an erroneous diagnosis of extra-uterine pregnancy, and as such presented it before his class. He had passed the sound into one horn of the uterus to demonstrate, as he thought, the extra-uterine pregnancy, and he was only prevented from making a serious blunder by observing the contractions under his hands of the pregnant uterus, and the delivery followed a few days afterwards. The diagnosis in these cases frequently becomes difficult.

Dr. Kelly, of Philadelphia, said he had seen six cases, of which one was recorded in the *Medical News*, a uterus septus with vagina septa. The introduction of the Goodell speculum plainly showed the menstrual fluid coming away in drops from each half. He had one case of vagina subsepta, the lower portion of the vagina being divided, whilst the upper was normal. This case presented some difficulty in coition. In another case he removed a parovarian cyst, since which time the patient conceived and passed an ordinary labor. He would call attention to one peculiarity as a means of facilitating diagnosis in bimanual examination, namely, the depression of the fundus in double uterus. Also the flattened shape of the fundus may be recognized in another form, as the famous case of undeveloped uterus of Rokitansky.

Dr. Franklin N. Martin, of Chicago, read a paper on

The Value of Galvanism as applied by Apostoli in the Treatment of Fibroid Tumors of the Uterus.

After briefly recounting the history of this method, with its growing success both in the new and old world, the author describes his improvements as made in the construction of the intra-uterine electrode, by means of which an exact dosage can be attained. The surface of the endometrium exposed to the galvanic current is accurately determined by the size of electrode employed, those used by the author measuring two and four square centimetres respectively. He also exhibited the large abdominal electrode, consisting of a hollow metal disc filled with water and covered by animal membrane, as an improvement over the cake of clay employed by Apostoli. After briefly reviewing the history of cases thus treated by him, the author stated that from January 1, 1887, to January 1, 1888, he had used galvanism over fourteen hundred times in the treatment of fibroid tumors, 653 times in fifteen cases. Of these five were completely cured and five symptomatically benefitted. After describing the method of using the galvanic current for the treatment of tumors the author concluded his paper with the following summary:

1. A means of generating a continuous current of electricity of steady and uniform character, that can give an actual current strength through a resistance of two hundred ohms of five hundred milliampères, is necessary in order to obtain all the benefits of this treatment.

2. Fibroid tumors of small size can be completely absorbed by the proper application of strong currents of galvanism.

3. Hemorrhages from hemorrhagic fibroid tumors can be promptly cured by the local coagulating effect of the positive pole when it is applied intra-uterine. Severe neuralgias, so often accompanying these troubles, can invariably be relieved by three or four applications of this treatment.

4. When the cervical canal cannot be entered by any form of intra-uterine electrode, flexible or otherwise, after repeated trials, a negative galvano-puncture should be made into the presenting part of the obstructing mass of the tumor and an artificial canal opened, which is to take the place of the impenetrable uterine canal in all subsequent treatments.

5. The intra-uterine electrode should in all cases be negative, unless there is hemorrhage or excessive leucorrhœa, when the positive pole is always required. The same patient may, however, present symptoms demanding the use of both poles at successive operations.

6. The strength of the current should depend entirely upon the amount of active surface of the internal electrode, and should be twenty-five milliampères for each square centimeter of active surface in actual contact with the endometrium. If more is used the concentration of the current will be sufficient to cause troublesome cauterization; if less is used the concentration will not be sufficient to cause the necessary coagulation for checking hemorrhage.

7. The duration of the treatment should be five minutes of the maximum current required.

8. The number of operations is necessarily dependent on and influenced by the result to be accomplished. A severe hemorrhage can be checked and symptomatic relief can often be accomplished by four or five seances, while a general reduction of the tumor necessitates many operations, varied, of course, according to the size and location. In some

cases of large multiple tumors a relief of symptoms, or symptomatic cures, must be accepted as a substitute for an actual cure.

9. The operation should be intra menstrual, if possible; if hemorrhage is continuous, however, operate during flow. The seances can occur as often as every day with the system of concentration adopted that enables one to attack different portions or the canal at succeeding treatments, or this can be given with advantage as few as once a week.

10. Since the adoption of the flexible intra-uterine electrodes and Dr. Apostoli's vaginal galvano-puncture, extra-uterine puncture should be regarded, if at all, only as a last resort.

11. Galvano-puncture needles and the internal electrodes should be constructed of material that is not injured by coming in contact with strong carbolic acid, or 1:1000 bichloride mercury solution. All internal electrodes should be thoroughly scrubbed with a nail-brush and soap and water after each application, and allowed to remain in one or the other of these standard antiseptic solutions until they are to be employed again, when they should be washed in a weaker solution of the same before using. Before a vaginal puncture is made the vagina should be thoroughly wiped out with a 1 to 3000 bichloride solution.

12. There is no excuse for any percentage of mortality in the proper application of this treatment. While Dr. Apostoli had two deaths in two hundred and seventy-five cases, he candidly admits they were due to avoidable accidents rather than to any legitimate procedure of the operation.

13. In experienced hands, and by the adoption of the present means of concentration, the most delicate and sensitive patient can receive, without experiencing any severe discomfort, all the benefits to be derived from this valuable treatment.

Dr. A. B. Carpenter, of Cleveland, O., next described a

New Method for Supplying the Electrolytic Current in Uterine Fibroids.

The author spoke of the difficulty of keeping the ordinary physicians' batteries in good running order, and therefore devised a method of supplying the electric current at any time desired in the proper strength. He took his current directly from the street, using the electric current as furnished by the Edison light for this purpose The Brush light is too dangerous, but the Edison system, which furnished an electric intensity of 100-110 volts, will not prove dangerous even with the entire strength outside of the rheostat.

The author exhibited the working of his apparatus, with the wires attached from the street.

In opening the discussion, Dr. Newman said that the electric current has always an electrolytic action, the amount depending on the strength used. If the current be small, the current will act as an absorbent; if large, it may prove destructive. He formerly claimed that a strong current should never be used, but in the light of recent developments he took it all back in considering the treatment of fibroid tumors, the large electrode diffusing the strength of one pole over the whole abdomen, overcoming the destructive tendency of a current of too great an intensity. The result will depend upon the concentration of the current upon the electrode. It is true that operators differ as regards the *modus operandi* in their treatment of tumors by electricity. Freeman, for instance, achieved good results with pointed needles. The speaker would, however, warn beginners against using needles with fine points, even in intra-uterine puncture, because it might be followed by fatal results. He himself used an intra-uterine sound, insulated, except at the end, to the depth of the uterus. This he attached to the negative pole and gradually passed it into the womb. If the canal be tortuous, this passing in may, at first, be difficult, but gradually the sound will enter deeper. The opponents to the use of electricity for this purpose say that it does not always cure them. He would reply that the object is not to entirely remove them, but to diminish the size as much as possible, so that they become harmless. If more than this can be done, so much the better.

Dr. Marcy, of Boston, said that for his knowledge of the use of galvanism, for its electrolytic action in tumors, he was first indebted to Dr. Cutter, of New York, whose pupil he was. At that time he saw cases benefited by this treatment, but also saw occasionally dangerous results. He then discarded its use, and was with great difficulty re-converted, until he heard of Apostoli's great success. He then again supplied himself with an electric apparatus, and since then had had unqualified success. If we could utilize the street lamps for this purpose, he regarded it as a great improvement, altogether a new departure. In conclusion, he greatly lauded the advances made by the two gentlemen in this direction, throwing additional lustre upon American gynecology.

Dr. Martin, in reply to a question, stated that the only improvement in his

animal membrane electrode consisted in its greater cleanliness and handiness. His dynamo enabled him not only to obtain high tension, but also a cautery current.

Dr. Carpenter, in concluding the discussion, stated that he always began with a low dosage. He thought it better to employ a longer sitting and reduction of strength in the beginning. Antiseptic precautions should also be instituted. He laid special emphasis upon the importance of rest after each seance. It is his practice to keep his patients at least one hour in his office before permitting them to leave. The great relief afforded at each sitting will often induce women to visit their friends and thereby frequently set at naught all good effects obtained. In conclusion, he narrated an intractable case of vesical irritation, in Cincinnati, which was truly in a pitiful condition. After four treatments the incontinence of urine entirely disappeared and the patient became greatly relieved.

One of the most instructive, as well as entertaining features of this session was the exhibit of micro-photographs, illustrating microscopical

Studies of Endometritis, Adenoma and Carcinoma Uteri

By Dr. E. W. Cushing, of Boston.

The pictures were thrown upon a large canvas from the stereopticon, and were very beautiful. Each picture was graphically and lucidly explained by the exhibitor.

Special Correspondence.

LETTER FROM CINCINNATI: MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

Wednesday, May 9, 1888.

The second day of the Association meeting has been especially distinguished by the report of the Trustees of the Journal, which contained figures indicating that the income of the Journal had increased last year, and that the outlook for its prosperity is very good. I am betraying no secret when I say that there is a deep dissatisfaction on the part of many of the members of the Association here with the way the Journal has been conducted; and there is a feeling that if its increased revenues have been secured by the abuses of its pages by advertisers during the past year, the Association cannot congratulate itself upon this fact.

I hear a great deal of complaint that the Journal is not what it was intended to be, namely, a substitute for the volume of transactions. Men complain that the proceedings of the Association are not properly reported in the Journal, and that the papers are not published in regular order or according to any well arranged plan. They say here that it is too much filled with the proceedings of the Chicago and Illinois societies, and that papers read at the meeting are pushed aside in order to make room for papers which have not been presented to the Association at all, and which were written long after the ones which they have displaced.

In connection with the complaints against the way the Journal has been conducted, much comment has been excited by the fact that the manufacturers of the Ivory Soap have circulated broad-cast at this meeting *fac simile* copies of a letter by Dr. N. S. Davis, endorsing and recommending this soap for use by physicians.

To return to the meeting: Dr. E. A. Wood presented on Wednesday a report from the special committee on dietetics. Dr. Wood has undertaken the work of interesting the Association in this important subject, and his labors were crowned with signal success. His report was listened to with deep attention, was received with the warmest expressions of approval, and its reading was followed by the adoption of a resolution making *Dietetics* one of the regular subjects for discussion at the annual meeting.

The social feature of to-day was a handsome reception by the members of the profession in Cincinnati to the members of the Association at the Art Museum, in Eden Park.

Thursday, May 10.

Among the proceedings of the general meeting to-day Dr. E. M. Moore, of Rochester, N. Y., read the annual address on surgery, which was a very interesting and scholarly document. The committee on the Rush monument reported progress, but announced that the responses to the recommendation of the Association that the members contribute liberally to the proposed monument had been far from satisfactory. The report of the Treasurer of the Association was read and approved.

The section meetings were interesting and well attended; and in the evening a delightful concert was given to the members of the Association and their friends in the Music Hall. This was very largely attended, and was one of the most successful entertainments of the meeting.

It was made known to-day that the Nominating Committee have selected Newport, R. I., as the place for the next meeting, Dr. Dawson, of Cincinnati, for the next President, and Dr. Pepper, of Philadelphia, to deliver the address on General Medicine. The latter choice is supposed to be intended to make up for the failure to accept an invitation to take the Association to Philadelphia next year. The choice of the place for the next meeting has been perhaps the most exciting question before the Association this year. The delegates from the Philadelphia County Society came here bearing a unanimous invitation from their Society to the Association to meet in Philadelphia in 1889. This invitation was understood to be tendered for the purpose of testifying to the good will of Philadelphia toward the Association, and of renewing the friendly relations which had been impaired by certain occurrences during the last few years. There can be no doubt that it would have been accepted, but for the fact that a few medical men from Philadelphia worked hard against it, claiming that the invitation was offered in order to get an opportunity to snub them and a college in which they are interested. It is believed that this fact, together with some arrangements in connection with the name of a candidate for the Presidency, prevented the acceptance of Philadelphia's invitation. Another thing which had some bearing upon the case is the fact that the delegate chosen to represent New Jersey, although instructed by his delegation to vote to go to Philadelphia, actually voted and spoke against this proposition! It is said that his conduct will be inquired into when he reaches home. Those who have heard of it here have expressed considerable indignation at this and other things which are reported of him. If what is asserted of him be true he may well be disciplined by his local Society. If it be erroneous, an explanation from him would probably be appreciated by his colleagues who are here.

While on the subject of the choice of the place for the next meeting, I may say, that this one has been marked by a degree of good-feeling which it is pleasant to note; and, so far as Philadelphia is concerned, there is apparently a complete restoration of the peace between it and the Association, which was of late so disturbed. The invitation which was not accepted was fully appreciated, and I have no doubt it would have been accepted if this had rested with the Association instead of the Nominating Committee.

Friday, May 11.

This was the closing day of the meeting; and, as usual, there was a comparatively small attendance. The business was hurried through; a few attempts were made to get in special resolutions; and an adjournment was effected after the passage of a hearty vote of thanks to Dr. Garnett for the admirable manner in which he has presided over the meeting. This resolution was not a mere form; for the proceedings this year have been entirely orderly and decorous, and have presented a marked contrast to certain others which it might seem invidious to specify.

One of the interesting episodes of the closing hours of the meeting was the introduction of a resolution by an ex-President of the Association — who is said to be a stockholder in a large manufactory of pharmaceutical preparations — that hereafter there should be no exhibit of pharmaceutical and surgical appliances. The reason given for presenting this resolution was that the exhibits distract the attention of the members of the Association from its own business. Certain of the unbelieving here have been so irreverent as to connect the resolution of the ex-President with the fact that the firm, with which he is said to be associated, has no exhibit here.

I cannot say how all these things may be; but this episode contributed materially to the interest of this meeting, and gave rise to some very amusing speeches. The outcome has been that the Association voted down the ex-President's resolution and pronounced most emphatically in favor of exhibits, and the exhibitors go away rejoicing.

So closes what has impressed me as a very successful meeting of the Association. Much good work has been done and I think I have seen the promise of much more to come. As you requested me to limit my correspondence as much as possible to the social and administrative features of the meeting, I have said very little about the scientific proceedings; but I may state in closing, that they appear to me to have been of unusual excellence. This I find is the general opinion, so that the meeting at Cincinnati is likely to be memorable in every way.

Yours truly, J. C. B.

—Dr. Henry Mitchell, State Inspector of the Board of Health, of Asbury Park, has resigned from the local board, of which he was President for eight years. The Borough Commissioners have passed a series of resolutions regretting the doctor's retirement.

Periscope.

Etiology of Floating Liver.

In the *Berliner klin. Wochenschrift*, No. 38, 1887, H. Rosenkranz reports the case of a woman, forty-eight years old, who was at the climacteric and had had eight normal births. In the middle of February, 1887, she was suddenly taken sick with violent vomiting and pain in the pit of the stomach and around the liver. Soon afterwards ascites, œdema of the limbs, genitalia, and skin of the belly occurred. The urine was free from albumin, the heart normal, and there was no jaundice. Through the administration of diuretics and hydragogue cathartics, the ascites and œdema soon disappeared. The general feeling of the patient was good. In May the abdominal cavity was found by repeated examination to be filled with a large tumor, which from its form and mobility was recognized without difficulty as the liver. The gall bladder and all the lobes of the liver could be plainly felt on palpation. The normal area of liver dulness had disappeared. It was now easy, says Rosenkranz, to explain the ascites and œdema. The violent vomiting had effected the separation of the liver from the diaphragm, and hence the violent pain at that spot. The absence in this case of pendulous abdomen is especially noteworthy.—*Centralblatt f. d. med. Wissenschaften*, April 14, 1888.

Boldine, a New Hypnotic.

The glucoside boldine, which is contained in boldo leaves, is said, by French experimenters who have studied it, to have hypnotic properties. It is easy to take, has no bad after-effects, increases the appetite and at the same time strengthens the patient. Doses of seventy-five and one hundred and fifty grains were administered to different patients by Juranville daily, without injury resulting. The sleep which is induced is like natural sleep, and respiration is regular and quiet. Excited, hysterical and other nervous patients who had suffered for a long time with sleeplessness, sank into a refreshing, quiet slumber under the use of boldine. It is given in capsules containing three grains, or hypodermically dissolved in water.—*Deutsche med. Wochenschrift*, April 19, 1888.

Diseases of the Aortic and Mitral Valves of Long Duration.

At a meeting of the Clinical Society of London, January 27, Dr. J. Kingston Fowler described this case, which was that of a man 66 years old, a wood-turner, working a treadle lathe. Physical examination of the chest gave the following results: There was a systolic recession of the epigastrium; the cardiac apex was in the fifth interspace in the nipple line; the impulse was forcible, indicating a moderate degree of hypertrophy of the left ventricle; at the apex the first sound was accompanied by a systolic murmur; at the base, in aortic area, there was a short systolic *bruit*, and the second sound was replaced by a rough diastolic murmur; there was evidence of some hypertrophy of the right ventricle; the valves on the right side of the heart were judged to be competent. The pulse was 84, small and collapsing. The urine was free from albumin. The interest of the case centred in the fact that in 1834 the patient, then a boy aged 13, was admitted into the Middlesex Hospital, under Dr. (afterwards Sir) Thomas Watson, with acute rheumatism, for which he remained under treatment nearly nine months. During the early part of the illness leeches were applied to the præcordium on more than a dozen occasions, and subsequently blisters were frequently used. The evidence upon which it was concluded that the valve lesions now present occurred during the attack of acute rheumatism in 1834 was entirely circumstantial, no written evidence of the case having been found. It might be summarized as follows: 1. The statement of the patient that on a certain occasion two gentlemen accompanying Dr. Watson on his visit, having auscultated the patient's chest, the one remarked that he heard a sound "like an old woman blowing a bellows in a back room;" the other said the sound was more "like to the whistling of a steam engine." 2. The fact that Dr. Watson told the patient's mother on his discharge from the hospital that he was never to leave home without telling her where he was going. 3. That for three years the patient carried a card with his name and address upon it, so that "if anything happened to him suddenly it might be known who he was and where he lived." 4. That he had had no return of the rheumatic attack, and had scarcely been absent from work for a single day during the last fifty-four years. The case was reported as being a rather remarkable example of a stationary lesion of the cardiac valves of rheumatic origin, in which compensation having been established, it had remained perfect for fifty-four years, and now showed no sings of failure. The patient had been shown at a previous meeting of the Society.—*British Med. Journal*, February 4, 1888.

Use of Pessaries.

Dr. Wallace A. Briggs, in a paper read before the Sacramento Society for Medical Improvement, February 21, 1888, says that pessaries must always be regarded as foreign bodies and their irritating qualities reduced to a minimum. This is to be accomplished: 1. By using thick, polished, non-absorbent pessaries. A rough absorbent surface not only irritates mechanically but also furnishes conditions extremely favorable to decomposition and consequent chemical irritation and even septic infection. A pessary with thin bars is much more likely to abrade and perforate the vaginal walls and to interfere with the pelvic circulation than one with thick bars. 2. By educating the vaginal mucous membrane and the neighboring tissues to a tolerance of the pressure, friction, and other causes of irritation consequent on the use of pessaries. This may be done by the use of either antiseptic cotton or antiseptic lamb's wool support. Either of these materials, indeed, but especially the latter, on account of its elasticity, makes an admirable pessary. Previous to packing, astringents, either in powder or in solution, may be applied to the vagina for the purpose of "hardening" it. Some prefer the use of elastic pessaries to test the tolerance of the pelvic tissues. He has not, however, found them altogether free from objection, and ordinarily prefers the antiseptic packing. 3. By accurate adjustment. By no means should the instrument be too large, otherwise the vagina will be unduly distended, irritated, inflamed, eroded, perhaps perforated, and the functions of neighboring organs seriously interfered with. Accurate adjustment relates to form as well as to size. Sharp angles should be regarded with suspicion, if not altogether discarded. One should never attempt to accomplish too much with the first pessary. 4. By occasional, sometimes frequent, removal of the pessary. In this way we obviate the evil effects of continuous pressure. In properly selected cases, therefore, instruct the patient to remove the pessary every third or fourth night on going to bed, and to introduce it again in the morning before rising. In the interval, position may be relied upon to keep the uterus in place. 5. By thorough cleanliness secured by daily cleansing and occasional antiseptic irrigation of the vagina.

Not only, he says, must pessaries be regarded as foreign bodies, but their contra-indications must also be kept well in view. To the neglect of these, he thinks, must be ascribed much of the prevailing doubt as to the value of pessaries. Among these contra-indications may be mentioned fixation of the displaced uterus; either acute, subacute, or some forms of chronic inflammatory affections both of the uterus and of the uterine annexes. Minor contra-indications consist of catarrh and erosions of the cervix, excessive weight of the uterus whatever its cause, extreme flexibility of the uterine walls, and vaginitis.

The author closes his paper with notes of several cases illustrating the benefits which accrue from the use of pessaries in appropriate conditions.—*Sacramento Med. Times*, April, 1888.

Treatment of Loose Cartilage in Knee-joint.

At the meeting of the Harveian Society of London, February 2, 1888, Mr. Herbert Allingham reported a case in which he had sutured the internal semilunar cartilage of the knee to the head of the tibia. The patient was a man, 35 years old, who had been constantly laid up by the slipping of the internal fibro-cartilage of the knee-joint. An incision two inches long was made, with its centre over the cartilage. The knee-joint was opened, and a strong catgut suture passed through the fibro-cartilage and the periosteum of the upper end of the tibia. The joint was washed out with carbolic lotion, and the synovial membrane united with deep catgut sutures; the wound was then closed without drainage. The patient, who was shown to the Society, made a good recovery, and can now follow his employment.—*British Med. Journal*, Feb. 11, 1888.

Pulsating Pleurisy.

A. Keppler, in an article in the *Deutsches Archiv für klin. Med.*, XLI, Heft 3, states that most of the cases of pulsating pleurisy occur on the left side; in a case of Eichhorst's, however, the pleurisy was on the right side. Keppler believes that the condition which occasions the phenomenon is brought about in the first place by a paralysis of the intercostal muscles, which is especially apt to occur in purulent pleurisy. Other factors in its development are a certain pressure under which the exudation exists, which is conditioned especially by sacculation of the latter; and finally, a sufficient power in the movements of the heart. Of course, an airless lung placed between the heart and the exudate is especially adapted to the unaltered propagation of the pulsating movements. As the pulsations are for the most part general, they are differentiated in this way from the pulsations occasioned by aneurism.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., Editor.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of The Medical and Surgical Reporter is published in each number. The edition for this week is 6,500 copies.

THE AMERICAN MEDICAL ASSOCIATION.

The thirty-ninth annual meeting of the American Medical Association which has just been held in Cincinnati was one which may justly be a source of satisfaction to all the friends of the Association. The scientific proceedings included important papers and discussions by men from all parts of the country, and were unusually full and interesting. The subjects ranged from those of the broadest and most general interest to those of minute and special detail. One of the most valuable addresses was undoubtedly that of the President, Dr. Garnett, who gave a clear picture of the present state of medical education in the United States, and urgently recommended the adoption of suitable legislation to regulate medical education by State authority, and to confine the right to issue licenses to practice to State Examining Boards. The details of this address include some points in regard to which there may be some difference of opinion; but the general principles of it can hardly be dissented from.

Other subjects of general interest were introduced and discussed by other members of the Association. For example, there was an important discussion on pneumonia, in the Section on Medicine, and a sort of symposium upon inflammation at and near the vermiform appendix, in the Section of Surgery; and a very remarkable paper and experimental demonstration by Dr. N. Senn in regard to determining the fact and location of perforations of the intestinal tube in cases of gunshot wound of the abdomen. The Section on Obstetrics and Diseases of Women was largely attended, and its work of the most instructive and interesting character. The same may be said of almost all the sections, while especial mention might be made of the work accomplished in the new Section on Dermatology and Syphilography.

These departments of the Association all showed a high degree of activity, and demonstrated their great usefulness. In the general meetings very little besides routine work was done. The business of the Association was transacted smoothly and satisfactorily. The most interesting subjects considered were probably the conduct of the Journal of the Association, and certain proposed amendments to the Constitution which provide for placing a large part of the administrative business of the Association in the hands of a permanent committee. The latter proposition was laid over for further consideration until the next meeting. The former subject was not discussed openly, although it was very warmly discussed outside of the meeting.

The general affairs of the Association seem to be in good condition. The discord which has so recently exercised an unfortunate influence upon the prospects of the Association seems to be fast disappearing. Some parts of the profession which have been alienated from the National Society appear to have determined to let the past go, and come back loyally to the Association, while the Association itself seems willing to give them a hearty welcome. At no recent meeting has so little of the unfortunate influence of agitation been apparent; and at

none has there been so strong evidence of the good sense and warm hearts of the members of the profession all over our land.

In looking over the whole of this meeting, we feel that there is every reason to congratulate the Association and the members of the medical profession in general, upon the cementing of friendship and advancement of scientific knowledge which it has brought about; and we may look forward with bright hope to the future, expecting the American Medical Association to be—as its originators designed it to be—the chief agent in developing unity of sentiment and increase of scientific attainment among the members of the medical profession in America.

A POINT IN REGARD TO INSANITY AND ITS TREATMENT.

The daily papers of May 1, 1888, report the fact that a clergyman who committed suicide at White Plains, N. Y., on April 29, had some time before confessed to his physicians that he was suffering with melancholia, and had an almost irresistible impulse to shoot himself. It appears, also, that he had already once made an attempt to take his own life, and that his father and brother had committed suicide.

This painful occurrence calls attention to the importance of having persons afflicted with melancholia under adequate surveillance, so that they may not have opportunity to carry out the insane impulses to which they are so peculiarly liable. It is a fact well known to alienists that persons afflicted with melancholia are apt to pass with frightful rapidity from a state in which they suffer with mere depression of spirits into one in which they become dangerous to themselves or to others. Occurrences similar to that mentioned above are so common that it seems utterly inexcusable for physicians to neglect to insist that the friends of persons who develop melancholia should adopt precautions adequate to prevent them. It may at times seem almost cruel for medical men to tell the friends of those under their care that nothing but the restraint of a hospital for the insane can be relied on to save a person with melancholia from doing violence to himself or to others; and yet there is no other way to prevent such catastrophies as must have come under the observation of almost every medical man.

Fortunately, in these days the fictitious horrors of insanity are being dispelled, and it is coming to be regarded as a true disease, which is often amenable to judicious treatment; and subjection to the discipline of a hospital for the insane is not now-a-days regarded as an incarceration. It is not nearly as shocking as it once was to propose this plan of dealing with those whose minds are unbalanced, and medical men should encourage the further growth of a rational sentiment in regard to insanity by showing that they regard it as a disease, and do not shrink from suggesting what they know to be the only reliable means of dealing with it.

By taking a proper attitude toward this whole subject, and making their opinions known to the community, medical men may do a great service to their fellow-men, not only by making it easier when the occasion arises to apply these opinions, so as to avert a threatening disaster, but also by bringing others to regard diseases of the mind with less distress and despair. The ways in which a more rational appreciation of the condition called insanity may be of value to those who suffer with it, as well as to their friends, are too numerous to be mentioned here; but we commend the subject to the reflection of our readers, in the hope that they will give it careful thought, and see if it does not suggest a distinct opportunity of usefulness to their fellow-men.

THE HOUSETOP AS A HEALTH RESORT.

The suggestion to utilize the roofs of city houses as a place of escape from the noise and unwholesome conditions of the street-level is by no means a new one. It has been not only made before now, but also acted on; and several large cities have popular resorts high up above the level of the ground, and to be reached only by steam elevators. But, lately Dr. Gouverneur M. Smith, of New

York, has proposed that the roofs of city houses shall be systematically occupied, for the sunlight and fresh air which can be there obtained, and has urged the devising of some plan by which it can be made feasible.

This proposition is one which deserves attention. Unfortunately Dr. Smith makes no suggestion of a plan himself, and no plan has ever been suggested which is of general applicability in the climate of a large part of our country. So, it is hardly likely we think that the day will ever come when a city in the United States shall have its roofs comparable to those of the towns of Syria, which are sometimes called cities. But, we believe something is attainable in the direction of utilizing the roofs for obtaining the benefits of light and air. Access to the roof of every house ought to be as easy as access to any part of it—of course with proper safe-guards against accident to children. In fact, the roof of a house ought to be a sort of pavilion, with a covering which would admit light and exclude the storm in winter, and give free access to the air when the weather is warm. To secure these objects a costly structure would be needed, one with a covering made in part of strong glass, and immovable, so that the sunlight could pass freely through it in winter, and in part of some material light enough to be removed in summer, and strong enough to bear a load of snow in winter. To modify the roofs of many houses now built so that they would fit this description would be very costly; and to construct new houses with such roofs would put a hard strain upon buyers and renters of houses, most of whom cannot afford a larger investment than will furnish them living rooms enough. But we believe it to be not only practicable, but also very desirable for those who can go a little beyond their absolute necessities to make use of the opportunities for light and air which are afforded by their roofs. In winter they could be used as solariums, in summer as refuges from the heat, and in every season they might afford a most delightful place of recreation and amusement.

We commend this idea to the attention of our readers in the hope that some of them may be able to suggest a plan by which they can be carried out.

IMPREGNATION AFTER CASTRATION.

A question which has most interesting physiological aspects, and may have an important forensic bearing is: whether, or not, a man who has had his testicles removed has still, for a moderate length of time, the power of impregnating a woman. This subject has been discussed at different times by a few students of physiology and of medical jurisprudence; but it has never been absolutely settled. The natural presumption is that under these circumstances a man would not be able to impregnate a woman. But—strange as it may seem—this is by no means certain. On the contrary, as the Roman author, Varro, claims to have known an instance in which a castrated bull impregnated a cow, so there are some medical writers who claim that a castrated man may impregnate a woman. The most recent writer on this subject is Dr. N. Obolonsky, prosector in the University of Charkow, Russia, who discusses it in the *Vierteljahrsschrift für gerichtliche Medicin*, April, 1888, principally in connection with a curious set of fanatics called "Skopzen" in that country. These fanatics practice castration as a part of their duty; but are not thereby prevented from indulging in great sexual excesses.

Obolonsky has studied the subject alluded to historically and experimentally, and finds no reason to doubt that, for perhaps a month after removal of the testicles, spermatozoa may be present in the vesiculæ seminales, and may be ejaculated in sexual intercourse. The historical part of his study is interesting enough; but more interesting and more conclusive is his report of the results of experiments he made upon two dogs, which showed that living and active spermatozoa were found in one seven days after castration, and in the other a month after the date of this operation. Obolonsky points out the fact that there is no reason for supposing that the same thing might not occur in a man; and em-

phasizes the importance of this possibility in a medico-legal sense.

It would be extremely interesting if this line of study were taken up and followed out by some American investigator, and an attempt were made to learn for how long a time after castration living spermatozoa could be detected in the seminal ducts or vesicles of animals; and also whether or not sexual excitation would cause their ejaculation. It is not likely that the results of such a study would prove of frequent applicability to actual medico-legal questions; but there is no telling when this very improbable occurrence might take place. Meanwhile, the matter would be of great physiological interest, and might throw a useful side light on other and commoner aspects of the phenomena of sexual intercourse and reproduction.

CATHETERIZING THE MALE URETERS.

One of the boldest suggestions in the line of surgical diagnosis which we have ever seen comes recently from Axel Iversen, of Copenhagen, who in the *Centralblatt für Chirurgie*, April 21, 1888, proposes the operation of supra-pubic cystotomy and catheterization of the ureters, as a means of determining which kidney of a man may be affected with pyelitis. In making this proposal, Iversen points out the importance of being able to ascertain which of the two kidneys is affected in any case, and the unreliability of the methods hitherto used for this purpose. In women it is not very difficult to catheterize the ureters through the urethra; but in men this is impossible. Last January Iversen had a patient with supposed calculous pyelitis, upon whom he thought it desirable to do a nephrectomy, or a nephrotomy. Being unable to ascertain in any other way which kidney was affected, he performed supra-pubic cystotomy, and catheterized both ureters. The result of this investigation showed him which kidney was affected with pyelitis, but it also satisfied him that no further operation was advisable, and he abandoned the idea of doing either a nephrectomy or a nephrotomy, as he had intended. The cystotomy wound healed satisfactorily, and the patient was none the worse for the diagnostic operation.

Iversen is so satisfied with the result obtained in this case that he declares that he would unhesitatingly repeat the procedure in a similar case, and expresses the opinion that supra-pubic cystotomy is by no means a dangerous operation, especially when performed for a diagnostic purpose.

There can be little doubt that supra-pubic cystotomy is an operation which, when carefully and skilfully performed, is not so dangerous as to preclude its employment for the purpose proposed by Iversen; and there seems to be sufficient justification for resorting to it when no other measure furnishes the information necessary to decide which of two kidneys shall be operated upon, when an operation on one seems to be necessary. As yet it has not been practiced often enough in this country to make it appear so simple an operation as it appears to Iversen; but its merits are understood well enough to prevent his conduct and recommendation from seeming to be rash.

QUACK ADVERTISEMENTS IN RELIGIOUS NEWSPAPERS.

It is pleasant to observe that our editorials in regard to the abuse of the columns of religious newspapers by the insertion of advertisements of quack medicines have not fallen to the ground without effect. From different parts of the country we have received communications which indicate not only that our comments have met with the approval of our professional brethren, but also that they have been taken to heart by some of those at whom they were directed. Among others, we note that the *California Christian Advocate*, a Methodist paper, endorses what we have said, and stigmatises quack advertisements in religious papers as an abomination. The editor adds that he rejects many advertisements, but that they are not usually submitted to him and he is not responsible for the business.

We regret that this should be the case; for we feel sure that if it were otherwise, the

paper which he edits would not illustrate the practice which he deplores. But, even as it is, we are glad to see in him an ally in a cause which we believe to be a worthy one, and which needs friends among the clergy. We have no doubt that there are many editors of religious papers who feel, with the editor of the *California Christian Advocate*, the mortification of having their names associated with papers which publish unblushing falsehoods, and we believe that if they wish they can soon end their troubles. Indeed we are sanguine enough to expect that they will do this, and to look to them with a good hope as well as good wishes.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

DISEASES OF THE SKIN. A MANUAL FOR PRACTITIONERS AND STUDENTS. By W. Allan Jamieson, M.D., F.R.C.P.Ed., Extra Physician for Diseases of the Skin, Edinburgh Royal Infirmary, etc. With woodcut and eight colored illustrations. 8vo, pp. xiv, 546. Edinburgh: Young J. Pentland. Philadelphia: J. B. Lippincott Company, 1888. Price, $6.50.

This volume gives a clear exposition of the subject which it treats from an English standpoint. The author's ideas show the marked influence which the teachings of Hutchinson and Unna have had upon dermatology. The plan of the work is essentially that adopted in books of its class.

In regard to the natural oiling of the hair, the author considers that Liebreich's researches on lanolin lead to the conclusion that the hair itself secretes a cholesterin fat and is thus kept pliant. If this deduction is warrantable, it would raise the hair, as Jamieson states (and evidently accepts), to the position of a living structure, and the reported cases of sudden blanching, would not be necessarily either impossible or miraculous. The statement is made also, based evidently upon Unna's investigations, "that not only the papilla, but all the interior of the follicle, as far as the opening of the sebaceous gland duct, is capable of producing the hair." If this be confirmed it would, of course, have some bearing in the destruction of hair by electrolysis. In this operation a desideratum hitherto considered desirable has been the insulation of the end of the needle, so as to limit the electrolytic action to the papilla, and thus reduce the chances of scarring to a minimum; but according to the above view of the hair growth, such insulation, were it possible, would be a positive disadvantage. In describing the operation here referred to the author draws largely from the writings by G. H. Fox. The interrupter in the handle of the needle-holder, as suggested by Unna and here advised, is in our judgment not to be commended, being a disadvantage both to the operator and to the patient. When the current is thus broken there is always too much risk of disagreeable shocks, and these about the head are, it is needless to add, extremely unpleasant, and may in fact be even dangerous.

The name of "molluscum contagiosum" is retained, the author holding the common English view of its contagiousness. Herpes progenitalis is looked upon, in the majority of cases at least, as a sequela of some antecedent venereal disease, apparently through some persistent nerve irritability. This is in accord with Unna and Greenough—the correctness of the view we are, however, by no means willing to admit. To us a more rational explanation of its apparent frequency in those addicted to venereal pleasures is that in such individuals the slightest irritation about the genitalia excites solicitude, and a physician is consulted; whereas in those of correct habits this condition would probably give rise to no anxiety, passing away in a few days and thus escaping medical observation. In respect to Duhring's "dermatitis herpetiformis" the following appears: "Our acquaintance with cutaneous diseases will require to be more extensive and more precise before we can accept conclusions so sweeping as his; but the cases put on record are most valuable, and sooner or later will lead to more accurate knowledge." The colored illustrations, as is almost invariably the case in the text-books, are, in an artistic sense, poor, and do not add to the general excellence of the volume.

In the matter of therapeutics the author's views while sufficiently advanced are sound and conservative.

Correspondence.

Old and New Treatment of Pneumonia.

Editor Med. and Surg. Reporter:

Sir:—Acknowledging, with thanks, the notice in the Reporter of my recent paper on Pneumonia, allow me to say further to your readers that my purpose was not specially to advocate venesection, but to contrast the results of the now current method of treatment, which I characterize as stimulation and narcotism, with the practice of forty years ago, in which sedative and eliminative measures were used, among which local and, less often, general bloodletting has been proved to have positive value. My conclusion, based on observation and experience, and confirmed by statistics, is given as follows: "There is more room for question, on the basis of experience, between the treatment of forty years ago and pure expectancy, nursing the patient in bed without medication, than there is between the old practice and that which is now generally current." Yours truly,

H. Hartshorne.

Germantown, Philad'a.,
May 4, 1888.

Notes and Comments.

Fæcal Accumulation.

Dr. Julius Wesselowski, reports a case in the *Kansas City Med. Index*, March, 1888, in which a woman, forty years old, had been feeling bad for about two weeks. The patient had a peculiar ashy countenance, and a temperature of 103°; the tongue was coated, and the breath foul. She said her bowels moved every day, but not enough, although she had taken calomel, senna, jalap and salt. On examining her abdomen, he found it largely distended with gas and a very prominent lump in the right side of the body. After manipulating carefully, as even the slightest touch would produce indescribable pain, he made out a large accumulation of fæcal matter in the ascending colon. He injected into the bowel at first two ounces of glycerine every hour, and gave an injection of soap and water every hour. After six hours of hard work, he noticed that the lump, by easy manipulation, became softer and friable. The first good movement the patient had was in about seven hours after his arrival. As soon as she had a movement, which consisted of hard lumps containing graham flour and raspberry seeds, which she had eaten about two weeks before, she became easier. The gas passed off, and the temperature fell to 99°. The next day he learned that she had about six more movements during the night and morning. He examined her again at that time and found that the whole lump had disappeared. In a few days she was well. He advises never to give a purgative of any kind while the fæcal impaction exists.

Cocaine and Loss of Vitreous in Cataract Operations.

Dr. A. D. Williams says: As I have heretofore stated, the greatest benefit we get from the use of cocaine in operating on cataracts is the almost entire prevention of the loss of vitreous. Before the introduction of cocaine the greatest anxiety in cataract operations was the ever-present fear of rupture of the hyaloid membrane and loss of vitreous. Cocaine prevents this accident in an indirect way. It kills sensibility, and thus prevents all muscular action. In this way the patient is prevented from *squeezing* the vitreous out by violent muscular contraction. While killing the pain of the operation is a grand thing, the resulting or secondary effect is the greatest boon. Since using cocaine the loss of vitreous has been the rarest exception. Only very recently I operated on an old man in the usual way. The lens was easily delivered. In manipulating the cornea for the purpose of clearing the anterior chamber of all particles of lens substance, suddenly and unexpectedly a bead of vitreous popped up. I had to desist to allow the remains of the lens to be absorbed away. Had there been no cocaine used in this case the loss of vitreous would certainly have been "frightful," and very likely destructive. The patient made a rapid recovery and had a good result. This, so far as I remember, is the first loss of vitreous I have had since using cocaine.—*St. Louis Med. and Surg. Journal*, April, 1888.

Remarkable Tolerance of Bullet Wound of the Brain.

It is reported in the Philadelphia *Ledger*, April 21, from Owingsville, Ky., that a man named A. G. Owings, who had been shot on the 7th inst., died on Thursday from the effect of that wound. The ball from a 38-calibre pistol struck Owings in the forehead between the eyes, and penetrated to a depth of five inches. Owings felt so little inconvenience that, thinking the ball was only below the skin, he did not send for the doctor to remove it until the following Monday. In probing, the doctor extracted about a spoonful of brain, but did not find the ball. Still Owings felt but little pain, ate and slept as usual, and attended to his work until the morning of the day he died. He then, after a deep sleep, sank into a stupor, in which he died.

Formula for Migraine.

Dujardin-Beaumetz recommends:

Tincture of gelsemium.....f℥iij ¼
Simple syrup.....f℥viij

M. S. Dose—One tablespoonful three or four times a day.

Hydrofluoric Acid in Phthisis.

At glass factories the beneficial influence of hydrofluoric acid on tuberculous workmen has long been noted, and many attempts have been made to employ this agent in the regular treatment of phthisis. M. Garcin has cured thirty-five and relieved thirty cases out of a hundred by means of this acid; ten of the hundred died, and in fourteen there was no improvement. The patients sit for one hour a day in an atmosphere saturated with hydrofluoric acid. This saturation is effected by passing a current of air by means of a pump through a tank of gutta-percha containing nine and one-half ounces of distilled water, and three-fourth ounces of hydrofluoric acid —*Lancet*, February 4, 1888.

Abscess in Bulbous Portion of Urethra Following Gonorrhœa.

At the meeting of the Sacramento Society for Medical Improvement, Feb. 21, 1888, Dr. G. L. Simmons, Jr., reported a case in which an abscess in the urethra had formed four weeks after the appearance of the discharge. The patient, a young man, had used one of the many patent injections, and with entire success as he supposed, until he noticed a swelling just under the pubic arch. The discharge at that time had almost ceased. This swelling, which was accompanied by severe pain andfever, compelled him to seek medical aid. The injection was stopped, cold applications to the perineum ordered, and an antipyretic internally. An anodyne suppository was found necessary to control the pain at night. Though the acute symptoms moderated the swelling increased until the entire penis became three times its natural size, congested and resistant along its entire length, and the foreskin, which was naturally quite redundant, was painfully distended. Micturition was difficult. The least chordee was insufferable to the patient, and the strength of the anodyne was doubled to counteract the pain. Poultices, as hot as could be borne, were applied, when it became certain that the formation of pus could not be arrested. Under this local treatment, with quinine and iron internally, and opium by the rectum, the abscess broke on the tenth day. The opening was evidently in the bulbous portion of the urethra, as there were no symptoms connected with the neck of the bladder. The purulent discharge was quite free. The patient's general health continued remarkably good throughout the whole course of the abscess formation, and with the evacuation of the pus all the minor symptoms disappeared. At no time was there any vesical irritation or prostatic trouble. Under a mild injection, the gonorrheal symptoms which had again declared themselves, readily yielded. At the date of this report, one month from the time of the rupture of the abscess, Dr. Simmons says that there remains an infiltration about the bulbous portion of the urethra, which causes the penis to be somewhat bowed during vigorous erection. With this single exception his condition is perfect.—*Sacramento Med. Times*, April, 1888.

Pathogeny of Iodoform Delirium.

At the meeting of the Academy of Medicine of Paris, March 20, M. Jeannel made an interesting communication on the "Pathogeny of Iodoform Delirium." The application of iodoform produces, he says, unimportant or serious effects according to the state of the patients. Each time delirium has occurred in a wounded person treated with iodoform, M. Jeannel proved that the patient had suffered from an antecedent cerebral affection, either alcoholism, chronic meningitis or mental derangement. His observation enabled him to conclude that, (1) a wound on an individual not suffering from a constitutional infirmity, may be dressed with iodoform; (2) this may also be done if the patient be not suffering from a constitutional affection not cerebral; (3) iodoform applied to a wound on a patient affected with a cerebral constitutional malady, produces delirium of greater or less intensity.

Galezowski's Antineuralgic Formula.

The Paris correspondent of the *Pharmaceutical Record*, gives the following formula:

Menthol	gr. xij
Cocaine	gr. iv
Chloral	gr. ij
Vaseline	gr. lxxv

M. Ft. Unguentum. Sig.—Apply to the painful parts, and cover with muslin.

It is said to be especially useful in perior bital pains and in ophthalmic hemicrania.

Medical Society of the State of New Jersey.

The one hundred and twenty-second annual meeting of the Medical Society of the State of New Jersey will be held in the Heath House, Schooley's Mountain, on Tuesday and Wednesday, June 12 and 13. Treasurers of District Societies are requested to send the amount of dues of their respective Societies to Dr. W. W. L. Phillips, Trenton, on or before June 11. Abundant space has been provided for exhibitors of surgical instruments. There will be a complimentary banquet in the Heath House, Tuesday evening at 10 o'clock, to the delegates and visitors. Dr. John G. Ryerson, Boonton, N. J., is Chairman of the Committee of Arrangements. A very interesting series of papers and discussions is on the programme.

Celebration in Honor of Dr. Hiram Corson.

Dr. Hiram Corson, of Conshohocken, Pa., was given a complimentary banquet, April 25, by the Montgomery County Medical Society, in honor of his sixtieth anniversary in the active practice of medicine. Dr. J. K. Weaver presided. A number of distinguished physicians from all parts of the State were present. After the banquet and some preliminary remarks by Dr. Weaver, the latter called upon Dr. P. Y. Eisenberg to

respond to the toast "Our Honored Guest." In the course of his address he referred especially to the debt which the profession owed Dr. Corson for his advocacy of the treatment of inflammatory diseases and acute infectious diseases with cold.

In Dr. Corson's reply he referred to the early days of his career, and to the many men of mark of a former generation whom he had known. Speaking of the country as it was in his earlier days, and of the methods of travel, he said:

"To me, then a mere stripling, there was at the time of which I speak no Ardmore, no Bryn Mawr in Lower Merion, no Bridgport in Upper Merion, no Collegeville, Zieglersville or Pennsburg on the banks of the Perkiomen, no Lansdale or North Wales, no Fort Washington or Ambler on the Wissahickon; and, above all, no Conshohocken, East and West, with their thousands of people. Norristown was a mere village, noted only for its small academy, its court-house and prison, and its two-horse stage which made daily trips to Philadelphia. Then the postage on a letter in Pennsylvania was 10 cents, but if it were to be sent "away off" to Ohio, twenty-five cents was demanded. There was scarcely a bridge, save on the turnpike roads, over the rapid and oft-times swollen Skippack, Perkiomen and Wissahickon creeks, and even the Schuylkill river had to be passed through the water at its various fords, by the physicians in their rides by night as well as by day, and often at the risk of life. Dr. McLean, who practiced in Horsham earlier than the persons already named, was drowned while fording the Wissahickon below Reiffs mill. Physicians generally rode on horseback. For years I crossed the Schuylkill river at Matson's Ford—the present site of Conshohocken bridge—oft-times when the cold, almost freezing water came far up the horse's sides. Patients were widely separated and physicians were rarely able to see even their acute cases oftener than every other day. Consultations were rare. However fiercely death assaulted, we were compelled to confront him alone. Sorely did I feel this necessity, and how great was my relief when I could have the counsel of an experienced physician! In this isolated way, we worked along for many years."

On January 17, 1847, the Montgomery County Medical Society was permanently organized, and owes its present success largely to the untiring energy and zeal of Dr. Corson.

Following Dr. Corson's reply, there were a number of short speeches by the different physicians who were present.

NEWS.

—Dr. Joseph Bauer has been appointed Professor of Clinical Medicine in the University of Munich.

—Dr. C. S. Muscroft, of Cincinnati, died suddenly in that city, May 5. He was at one time President of the Cincinnati Academy of Medicine.

—Dr. Straus has been appointed successor to the late Prof. Vulpian as Professor of Experimental and Comparative Pathology in the Faculty of Medicine of Paris.

—Dr. C. D. Palmer, of Cincinnati, was seriously injured, May 6, by being thrown from his carriage while his horse was running away. It is feared that his injuries may prove fatal.

—The prize offered by the *Pharmaceutical Era* for the best essay upon the Mutual Relations of Physicians and Pharmacists, has been awarded to Prof. F. H. Gerrish, of Bowdoin College.

—In the *Boston Med. and Surg. Journal*, May 3, 1888, Dr. John Homans reports a case of ovariotomy for multilocular papilloma in a woman eighty-two years and four months old. He states that not a single case of ovariotomy in women eighty years of age or older had been previously reported. His patient recovered.

—The Camden County Medical Society held its annual meeting at Gloucester City, May 8, Dr. Gross presiding. Officers were elected as follows: President, W. H. Iszard; Secretary, E. L. B. Godfrey; Treasurer, A. M. Mecray; Board of Censors, Drs. John W. Snowden, H. G. Taylor, J. R. Stevenson, Alexander Marcey and H. E. Brannon. Delegates were also elected to the various conventions and national associations. At the dinner which followed, Dr. H. Genet Taylor was presented with a silver set as a testimonial of services of a quarter of a century as Secretary.

—A bill has been introduced into the Legislature of New York which provides that "it shall not be lawful for any person or persons to introduce into or upon any dead body of any person or human being any poisonous substance, organic or inorganic, for the preservation of the same, or any so-called embalming fluids or materials of any kind, which will, in any manner whatsoever, interfere with chemical tests which may subsequently be applied or made use of by chemists in medico-legal investigations."

HUMOR.

ETHEL USED TO PLAY A GOOD DEAL in the school class. One day she had been very quiet. She sat up prim, and behaved so nicely, that after the recitation was over the teacher remarked: "Ethel, my dear, you were a very good little girl to-day." "Yes'm. I couldn't help being dood. I dot a tiff neck."—*Presbyterian Banner.*

A REMARKABLE CASE OF HEREDITY.—A correspondent of the *N. Y. Medical Journal*, April 28, 1888, writes that a hydrocephalic child was born to an ultra-prohibitionist father, who said to the doctor:

"What is the matter with my child?"

"Why, it has inherited its disease from you."

"What do you mean?"

"Why, it has *water on the brain.*"

THE *Ft. Wayne Medical Journal* indulges in the following anent microbes:

Some M. D.'s are downright skeptics,
Devoid of faith in antiseptics,
The very name of microbe hate,
The chief of whom is Lawson Tate.

To this the *Medical Standard* adds: This is the most severe cut Tait has had to endure; nobody previously had ventured to insinuate that he was a microbe.

NEW DRUG CLERK—"Beg pardon, sir, but that young lady who just went out asked you for infant powder." Old druggist—"Yes," "But you gave her regular face powder." "Yes; I always make that mistake. That's how I got up such a big trade. If a woman really wants infant powder she will insist upon having it."—*American Hebrew.*

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hsopital Service, for the two weeks ended May 5, 1888:

P. H. Bailhache, Surgeon, to proceed to New York, N. Y., for temporary duty, May 1, 1888.

W. H. H. Hutton, Surgeon, detailed as President of Board to report as to quarantine establishment at North Chandeleur Island, Gulf of Mexico, May 4, 1888.

Walter Wyman, Surgeon, granted leave of absence for fourteen days, May 4, 1888.

G. W. Stoner, Surgeon, detailed as Chairman of Board for the physical examination of candidates for appointment and promotion, Revenue Marine Service, May 5, 1888.

F. W. Mead, Passed Assistant Surgeon, detailed as Recorder of Board for the physical examination of candidates for appointment and promotion, Revenue Marine Service, May 4, 1888.

H. R. Carter, Passed Assistant Surgeon, detailed as Recorder of Board to report as to quarantine establishment at North Chandeleur Island, Gulf of Mexico, May 4, 1888.

S. C. Deevan, Passed Assistant Surgeon, relieved from duty at Sapelo Quarantine; to assume charge of the service at Savannah, Ga., May 3, 1888.

J. H. White, Passed Assistant Surgeon, relieved from duty at Savannah, Ga.; to assume charge of Sapelo Quarantine Station, May 3, 1888.

Official list of changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from May 6, 1888, to May 12, 1888:

Lieutenant-Colonel James C. McKee, Surgeon, granted leave of absence for one month. S. O. 107, A. G. O., May 9, 1888.

Major Charles R. Greenleaf, Surgeon; Major Robert M. O'Reilly, Surgeon, and Capt. John O. Skinner, Assistant Surgeon, detailed as members of a board of medical officers to assemble at the U. S. Military Academy, West Point, N. Y., on June 1, 1888, to examine into the physical qualifications of members of the graduating class and of the candidates for admission to the Academy. S. O. 104, A. G. O., May 5, 1888.

Par. 11, S. O. 104, A. G. O., May 5, is amended by Par. 4, S. O. 108, A. G. O., May 10, 1888.

Major Charles R. Greenleaf, Surgeon; Major Robert M. O'Reilly, Surgeon, and Capt. John O. Skinner, Assistant Surgeon, are detailed as a board of medical officers to assemble at the U. S. Military Academy, West Point, N. Y., on June 1, 1888, to examine into the physical qualifications of the candidates for admission to the Academy, and, in connection with the Superintendent of the Academy and Commandent of Cadets, the members of the graduating class.

Major Harvey E. Brown, Surgeon, the leave of absence for seven days granted by orders 68, Fort Barrancas, Fla., May 2, 1888, is extended twelve days. S. O. 90, Div. Atlantic, May 8, 1888.

Capt. Leonard Y. Loring, Assistant Surgeon, granted leave of absence for three months on surgeon's certificate of disability. S. O. 105, A. G. O., May 7, 1888.

Capt. Paul R. Brown, Assistant Surgeon, granted leave of absence for six months, on surgeon's certificate of disability, with permission to leave the Division of the Atlantic. S. O. 107, A. G. O., May 9, 1888.

Capt. Robert B. Benham, Assistant Surgeon, to proceed from Du Chesne to Fort Douglas, Utah, and report to commanding officer of that post, not later than 25th inst., to accompany Battalion of 6th Infantry to Fort Lewis, Col. Upon completion of this duty, will return to his station, Fort Du Chesne, Utah. S. O. 33, Dept. Platte, May 5, 1888.

Changes in the Medical Corps of the U. S. Navy for the week ending May 12, 1888:

Passed Assistant Surgeon A. G. Cabell, detached from "Adams," and to proceed home and wait orders.

Surgeon M. H. Simons, detached from Naval Academy, and to Practice Ship "Constellation."

Medical Director P. J. Horwitz, leave of absence for six months to leave the United States.

A Naval Medical Examining Board is now in session at the Naval Hospital, Philadelphia, for the examination of candidates for admission to the Medical Corps of the Navy. There are eleven vacancies in the list of Assistant Surgeons. Permits for examination can be obtained on application to the Secretary of the Navy.

JUST READY.

Diseases of the Heart and Circulation in Infancy and Adolescence.

By John M. Keating, M. D., and William A. Edwards, M. D.

Large 8vo, pp. 215. All Booksellers.

FOR SALE.

Two-wheeled Doctor's Gig, nearly as good as new. Original cost $450. Price, $100 cash.

Apply to Hilly's Stable,
20th St. above Chestnut, Phila.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session in addition to four Didactic lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars see annual announcements and catalogue, for which, address the Secretary, Prof. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

CLEARING OUT SALE

—OF—

POCKET RECORDS.

We have on hand a small number of Pocket-Records prepared for the year 1887.

We would like to sell them, and in order to get rid of them, we will make the following offer; we will mail

A Pocket-Record for 30 Patients a week for 50 cents.
" " " 60 " " 75 "

This is Less than the Books Cost Us.

There is nothing the matter with them, but we want to clear them out.

ON THE TREATMENT OF CHRONIC DISEASES OF THE HEART.[1]

BY PROFESSOR M. J. OERTEL,
MUNICH, BAVARIA.

The pathological alterations of the heart muscle may pertain either to quantity or quality. The quantitative alterations have to do with either augmentation or diminution of the muscular mass of the heart. They affect either certain parts of the heart, or the entire organ. The augmentation of the muscular mass—*hypertrophy* of the heart—is rarely a primary affection. Almost always it is the consequence of obstacles in the blood current, and is due directly to overwork imposed on the heart by these obstacles. It is then a compensatory hypertrophy, a necessary hypertrophy, and as such it will not do to combat it; it will not do to think of reducing the size of the heart under such circumstances. On the contrary, this compensatory enlargement when it exists is to be respected and kept intact, and we should endeavor to reproduce it when it is enfeebled or lost.

Diminution of the muscular mass—*atrophy* of the heart—when it affects the entire organ, accompanies general disturbances of the nutrition; it is associated with a diminution of the quantity of the blood. Partial atrophy leads to dilatation of the thinned cardiac walls. The *qualitative* alterations of the heart muscle follow disorders of nutrition or processes of degeneration. The muscular fibre itself is diseased, it performs its functions badly, or it is destroyed. The gravest form is that in which the muscular fibre is destroyed by fatty degeneration, the result of prolonged super-alimentation, of marasmus, or of chronic alcoholism.

The character of chronic affections of the heart is always the same; we observe always a diminution of the cardiac vigor going on to insufficiency, and the symptoms are constantly those of troubles of the circulation: arterial anæmia, venous stasis, augmentation of water in the blood and in the tissues, consecutive renal affections, dropsy, paralysis of the heart. Consequently, the ends to attain by treatment are the following:

1. To make the heart sufficient for its tasks; to re-establish its vigor; to augment the muscular mass of the organ till a compensatory hypertrophy is obtained, which, at the same time, shall remedy any partial existing dilatation.

2. To regulate the disturbed blood current, as well as to restore the altered constitution of the blood.

The prognosis will depend on the nature and degree of the troubles of nutrition, and on the existence of complications.

Before taking up the dietico-mechanical treatment based on these principles, it will be worth while to glance over the history of the treatment of cardiac affections.

Albertini and Valsalva fully believed in the possibility of exercising a direct influence on the heart, notably on the hypertrophied and dilated heart. They ordered absolute rest, and a very severe debilitating regimen; blood lettings, frequently repeated—as often as the pulse became stronger; food reduced to the minimum, nothing more than a little broth several times a day being allowed. Laennec employed a similar treatment, but he applied it only to patients not yet cachectic

[1] A paper read before the Seventh Congress of Internal Medicine, held at Wiesbaden, April 10, 1888. [Prepared from Dr. Loewenthal's report (*Semaine Médicale*), by E. P. Hurd, M.D.]

or dropsical. I think it useless to attempt to show the folly of such treatment.

Later, the treatment became rather expectant and a careful attention to symptoms, but the blood lettings were continued. Absolute rest in bed was abandoned in favor of limited corporal exercises. With the exception of the blood lettings, this treatment has remained in force down to our own day.

Wunderlich began a reform by changing the indications of treatment. Along with the symptom treatment of the cardiac affection, he believed in the necessity of restoring the harmony between the vigor of the heart's contraction and the quantity of blood to be put in circulation. Only, he attempted to accomplish this by diminishing the quantity of the blood, and this is why he still prescribed blood-letting. Starting from a correct principle, he ended in an erroneous therapeutic result.

Stokes was the first to dare to attack the principle of absolute rest. He recommended physical exercises, which were to be gradually and systematically increased; journeys on foot in mountainous countries, as Switzerland and Scotland. As for diet, he prescribed substantial food, a great deal of meat, and but little fat. Despite their importance, Stokes's principles did not awaken attention; they were neglected in practice and in scientific studies. With the exception of the fact that they called forth angry protests in England and elsewhere, his propositions were simply ignored. Practitioners continued to insist on the necessity of sparing what remained of the heart's forces by prolonged rest, and of preventing an increase of fat by Banting's system.

It was during the almost absolute prevalence of these principles that I dared in 1875 to raise my voice in favor of endeavors to exercise a direct influence on the heart suffering from insufficiency, and restore lost compensation. I think that I have succeeded. The principles which have guided me are the following: To remove, by an appropriate diet, the troubles of nutrition; to improve the quality of the blood; to reduce the redundancy of water in the economy to its normal amount; to facilitate the encumbered work of the heart; to fortify the heart muscle in the direction of an augmentation of its volume; to raise the pressure in the arterial system; to regulate the exchange between the arterial and venous system; to unburden and relieve the kidneys; lastly, to maintain the re-established vigor of the heart by a reasonable dietary, and by gymnastics and other exercises, notably by mountain climbing. So then my treatment divides itself into two parts, the regimen and the mechanical part. These two parts are complementary to each other; there are very few cases in which the one is indicated without the other.

As for the matter of regimen, my method necessarily takes account, on the one hand of the general state of nutrition, and on the other, of the quantity of liquid accumulated in the vessels and tissues of the body.

Relatively to the general state of the nutrition, especially to the quantity of fat, we have to establish the following distinctions:

1. Much fat with plethora: the heart enfeeblement is but just commencing. The appropriate regimen will comprehend an increase of albumen in the food and a diminution of fatty substances, or substances which produce fat; little or no diminution of liquids.

2. Polysarcia, with serous plethora: augmentation of albumen, diminution in fatty substances and liquids.

3. Lipomatosis cordis, with hydræmia in aged persons; the albumen and fat of the body tend to diminish. Here you want to augment the ingestion of albumen. Continue and even *augment* the ingestion of fatty substances, and diminish liquids.

As for the mechanical part of the treatment, these are the principles:

In order that you may cause a muscle to become hypertrophied, it is not enough to augment the introduction of albumen into the economy, you must also augment the function of the muscle. This physiological principle, which is true for all the muscles, is no less true for the heart muscle. We should, then, endeavor to augment both the number and the force of the heart's contractures. We may arrive at this result by different means. Every muscular contraction, it matters not in what part of the body, influences equally the heart, arouses its contractions, and augments their number and force.

[Prof. Oertel here presented an instructive table showing the normal "hyperplasia" of the heart in animals subjected to much exercise, as cattle, horses, hares and deer, and the ratio of the heart to the body in such animals. This is contrasted with the ratio in men and animals given to rest rather than exercise. The working heart is larger, thicker and heavier, as might have been expected, and its ratio to the bodily weight, as a rule, is greater.]

Let us now glance at the phenomena witnessed in man after prolonged exercise in making ascensions. From these phenomena

we draw conclusions, establishing the fact of a higher nutrition, and an actual hyperplasia of the muscular fibres of the heart:

1. All the arteries dilate, and the blood pressure increases in the arterial system.

2. The contractions of the heart become stronger.

In gauging the work imposed on the muscles by the ascension of different heights with a scale varying from 1 to 20 degrees, and in more or less prolonging these tasks, adding to their duration as the strength may bear, we may graduate the influence exercised on the cardiac muscle, and adapt the treatment to each special case. The application of these principles has been made in the *land-cure stations* (Terrain-Kurorte) with which you are acquainted. Simple gymnastics and Swedish gymnastics, prescribed and applied with or without medicinal baths, also exercise undoubtedly a great influence upon the heart; but hill-climbing and mountain-climbing seem to me the most appropriate, calling into play as no other exercise does, the respiratory forces, and imposing on the patient a course of pulmonary gymnastics which enlarges the reservoir indispensable to the circulation of the blood in the lungs. Lastly, ascension-excercises put in movement the muscles of the lower extremities, force the venous blood from its favorite haunts of stasis, and thus directly combat the venous congestions, so sure to accompany cardiac failure.

To fortify the heart is not enough; we must also, as I have before said, diminish the work of blood-conveyance imposed upon the heart. Wunderlich has counselled to attain this result by reducing the total quantity of blood. I believe, however, that we may accomplish the same end by diminishing as much as possible the aqueous contents of the whole body without meddling with the albuminous contents of the blood. I attempt to bring this about by the following means:

1. By diminishing the quantity of liquids introduced into the organism with the food; this point I have alluded to before, while on the dietetic regimen.

2. By augmenting the secretions. The exercise of mountain-climbing augments the excretion of water, both by the enhanced work of all the muscles (elimination by the skin), and by the increased vigor and quickness of the respiratory movements. It is clear that the evaporation of water from the surface of the lungs must increase correlatively with the intensity of the respiration. The elimination by the skin may be also augmented by heat under all its forms: sun-baths, sand-baths, vapor-baths, warm-water-baths, etc. The diminution of liquids introduced into the organism along with the food is of itself attended with augmentation of the urinary secretion when the kidneys still perform their functions normally.

It must be obvious that a method which has so energetic an action on the heart and the entire circulatory apparatus, must sometimes encounter insurmountable obstacles to its application. It is clear, then, that great precaution is necessary in the application of this system to individual cases, and that no iron rule can adapt itself to all; the general principles of treatment, however, I believe to be sound.

In conclusion, the results which have been obtained by my system in places in which the "land-cure" method has been carried out according to my directions, have been satisfactory. I have received special reports from the following stations: *Ueran*, *Ischl*, *Reichenhall*, *Liebenstein*, *Baden-Baden*, *Abazzia*, *Kreuth*, and *Wilbad*.

These results have been as follows:

1. Exclusively favorable in cases of fatty heart — even when pronounced — without sclerosis of the coronary arteries, but with serous plethora, venous stasis, and often œdema. The patients were for the most part aged. The following consequences have been noted: The vigor of the heart returns, the heart-impulse and its sounds become more audible, the pulse, before irregular, becomes regular, the albuminous capital of the body augments, the fat diminishes, and often in a marked manner.

2. Augmentation of the muscular mass of the heart, even to the establishment of a compensatory hypertrophy: this has been especially apparent in valvular affections of the left ventricle, and where the pulmonary circulation has been embarrassed by affections of the dorsal spinal cord.

3. Disappearance of very marked dilatations when the primary affection (insufficiency or stenosis of the valves) is not of too long standing.

4. Restoration of the harmony between the arterial and venous circulation, augmentation of the quantity of blood and of blood pressure in the arterial system, diminution of the cyanosis, of the serous plethora and of the effusions, when the latter already exist.

5. Diminution and disappearance of the respiratory troubles.

Finally, these results seem lasting; they have persisted for years (in some cases from nine to twelve years), which proves that we have not had to do here with that spontan-

eous amelioration which sometimes supervenes without any treatment to disappear shortly afterwards, but with a real and permanent amelioration of this state of the heart muscle.

QUADRUPLE AMPUTATION; RECOVERY.

BY G. C. WALLACE, M.D.,
ROCK RAPIDS, IOWA.

In the REPORTER of April 7, appears a report of a case of simultaneous triple amputation performed by Prof. Ashhurst, in which I notice the statement that he has been able to find but one instance of quadruple synchronous amputation, and as it may be of interest to the readers of the REPORTER I send a report of a quadruple synchronous amputation which I performed the 27th of last January, together with a brief history of the case.

The patient was a German, sixteen years of age, weighing about one hundred and sixty pounds. He was frozen the night of January 12. Being at school on the 12th, he started home as usual, and was overtaken by the noted January blizzard. He lost his way and was out all night, and was picked up for dead the next morning, but noticing him make a slight noise, the men who found him took him to a school-house, about a mile distant, and there commenced trying to revive him by rubbing and applying kerosene oil. I was immediately sent for, but owing to the severity of the storm could not reach him until the morning of the 14th, when I found him in a semi-comatose condition, but entirely thawed out. I gave him some whiskey and quinine, and applied tincture of iodine and a solution of carbolic acid. In about forty-eight hours I had him taken home, and let him lie until January 27, giving him meanwhile elix. pyrophos. iron, quinine and strychnine, and applied part of a mixture of ung. petrol. ℥x, hydrastin ℥iv, ac. carbolic. ℥ij, once daily. On the 27th, I took off both arms about half-way between elbow and wrist, and the right leg about three inches above the ankle-joint, and the left foot through the first row of tarsal bones, leaving three of them, and cut off the heel, leaving the os calcis exposed for over one inch. The flesh was putrid, but I found the bone uninjured, and so left it for the flesh to grow on again (which it has now done). I operated on all the limbs before dressing any of them or taking up any arteries; I next took off the point of his nose. After operating, I used hyd. chl. cor. ℥iv, spt. vini rect. ℥iv; one teaspoonful of the mixture to one pint of tepid water, and washed each stump with this solution. Next I saturated some absorbent cotton with the same solution and applied it over each stump, covering this with oil silk.

I continued giving the elix. pyrophos. iron, quinine and strychnine, and discharged him on March 18, when the wounds were all healed up, except one place about as large as a dime; and at the present time he has gained several pounds in weight and claims that he feels as well as usual.

If any one knows of any other operation of the same kind I would be pleased to hear from him, and if any surgeon wishes to know anything further in regard to this case I will cheerfully furnish any information desired.

AN INTERESTING OBSTETRICAL CASE, WITH PECULIAR ANOMALIES OF THE CHILD.

BY T. L. TAYLOR, M.D.,
OF LISBON, DAKOTA.

Mrs. W., 25 years old, was taken in labor at her second confinement, about six o'clock A.M, April 20, 1888. The labor pains continued at regular intervals. I was called about 3 P.M. the same day, and found the bag of waters protruding through the os, which was dilated to the size of a silver dollar. I ruptured the membranes and the liquor amnii that escaped was of a greenish color and of a very offensive odor, and of the consistency of glycerine. I diagnosticated a breech presentation, and as labor progressed rapidly I brought down the feet and had the body delivered in a few moments. Now appeared the trouble. I noticed a deformity of the legs, feet, and the back at this time, and owing to the apparent inability to deliver the head I concluded that I had to deal with a case of hydrocephalus—which proved true. I inserted the first two fingers of my right hand into the vagina, and got them into the mouth of the child and flexed the chin, thus gaining quite a little ground. The patient then asked me to wait a few moments and she would summon all her strength and courage to help me; so when another pain came on, by our united efforts she was delivered of a male child without the use of any instruments, and without any laceration of the mother. I invited two of the medical men of our city to go over and see the child (which was still-born) the same evening, and

the following notes were taken: The length of child was 22 inches; its weight 11 pounds; the measurement from the occipital protruberance to the forehead was 12¾ inches; and from the former point to the chin was 14¾ inches; the measurement from temple to temple over the top of the head was 11¾ inches; the circumference of the head was 18 inches; the length of umbilical cord was 42 inches. The face was well formed, eyes, nose, ears and mouth were all in a normal condition. There did not appear to be any neck to the child, the head seemed as though set upon the shoulders. At the junction of the dorsal and lumbar vertebræ the spine bifurcated; at this point can be seen two distinct sets of spinous processes which extend to the pelvis. A sac containing about two ounces of serous fluid (hydrorachis) was attached to the back over the two spines. There was no deformity of the anus, but there was epispadias of the penis. The legs were deformed. There was talipes equino-varus of the left foot, and of the right foot talipes varus only. One half of the placenta was made up of small hydatiform vesicles containing a reddish fluid, and having the appearance of a bunch of grapes, while the other half was to all appearance normal. The cord was found wound around the body twice and around the neck twice. The patient has always been in a healthy condition in every respect; there has been nothing of specific origin in her or her husband's history. She tells me now that for the past three months at different times, although she has felt well, she has passed by the vagina pieces half the size of her hand, which looked like pieces of spoiled meat and had a very offensive odor. This is the second case of hydrocephalus I have had out of four hundred and ninety-six cases of labor at full term; both were in male children, both were still-born, and both mothers are living and well.

PROSTITUTION.

BY JANET E. RUNTZ REES.

Prostitution is generally looked upon as a necessary evil. The class of so-called "unfortunates" in every great city increases in direct proportion to its prosperous conditions, and, whether under special legislative control or not, exercises indirectly a terrible influence upon its social life. Those who are most forward in their efforts at rescuing the fallen and degenerate women, who are the offscourings of civilized communities, rarely look beyond the surface of the subject with which they are dealing, or, if they do, it is either with sentimental or religious horror at the impurity and loathsome details which are necessary accompaniments of missionary effort in this direction. Appeals are constantly made to public opinion or public sympathy in regard to the possible reclamation of fallen women, and the subject has so long been regarded from this standpoint that the question of "fallen" man has never yet, so far as I am aware, been discussed at all. It is to my mind of even greater importance than the terrible subject of diseased and prostituted womanhood, for the reason, that while the desecration of the one sex is directly traceable to the inflamed passions of the other, it seems impossible to ascertain how far sexual gratification is essential to robust manhood.

The institution of marriage would in itself appear to indicate the necessity of sexual intercourse for both men and women, for that, however, we may regard it, is the mainspring of conjugal relationship. If it were eliminated as a factor in married life, and the possibilities of intercourse between the sexes limited to the ordinary demands of friendship, if coition in itself were not a principal object of marriage, apart even from procreation, we could better understand upon what ground prostitution should be judged, and whether it should be condemned as sexual intemperance or indulgence only, or on account of the terrible results which ensue from it. We should better understand, in short, what *constitutes prostitution*, and in what sense licensed intercourse is better than unlicensed intercourse. As regards the moral question, as much contempt is expressed socially for the young woman who has, as it is said, fallen and lost her virtue for the sake of love, as for the shameless denizen of a public thoroughfare. This fact in itself is a prolific source of evil, for the ranks of the unhappy women whose charms are purchasable are recruited by those whose crime has often been the mere acceptance of a lover's caresses. If sexual intercourse before marriage is a crime for the woman, punishable, if *discovered*, by shame and contempt, involving the illegitimacy of offspring and life-long isolation for the mother, why is it at once not only justifiable, but an *absolute virtue* directly, the marriage knot is tied? The woman who *after* marriage repudiates sexual claims is blamed, while the girl, who in ignorant response to an indefinite longing, or in the excitement of incipient passion, hallowed by love, but not by law,

listens to the selfish reasonings of a promised husband, is held to be equally in fault, and far more heavily punished.

The *morality* of sexual intercourse is in itself a subject well worthy of consideration. Is it or is it not dependent upon marriage? And if it is, what excuse can be found for the men who, consider it in what light we may, are responsible for the existence of fallen women? If our cities and towns swarm with diseased women; if our village statistics show the births of hundreds of children owned by no father; if our insane asylums number among their inmates dozens of young girls and older women, distraught from loss of virtue, who but men have been the agents of these destructive elements? And if from the moral side of this terrible question we turn to the physical, what do we find? Unmarried girls paying the penalty of life-long suffering for the momentary gratification of a lover's lust; married women, dying by inches, because violated nature refuses to respond to the constant demands of rampant passion. This aspect of the question is a very terrible one. It is *in itself* one, and a very prolific source of prostitution. Statistics have proved that the men who frequent brothels and who support mistresses are more often than not married men. On the other hand, married women are often unfaithful, demanding more in sexual gratification than the husband is disposed to give, or simply obedient to that diseased appetite which is one result of a constant solicitation on the husband's part.

If society has ordained distinct codes of morality for men and women, nature has not. The physical punishment of an unchaste life visits the man almost equally with the woman, in premature decadence; and the woman who has fallen from virtue for the sake of the man, becomes in her turn the vehicle of disease to his fellow-man. How find a remedy for an evil so far-reaching, so imperative in its consequences? There would appear to be but one way, and that not a popular one, viz., by a consideration of prostitution upon its own merits or demerits, apart from social or family views of it—a consideration of its *fundamental* lawlessness on the part of man as well as woman, which must begin with a preliminary inquiry into its origin, growth and present potency. How far, in a word, is prostitution or unlicensed intercourse in itself a breach of nature's law, and as such punishable by suffering, disease and premature decay? And how far is it merely a social evil, to be regulated by law or by public opinion? What part does coition play in nature's plan? What justification exists for the prominent part it assumes in the lives of individuals? How can we best meet and overcome, or better still, obviate the results of sexual appetite, as shown in the unbridled indulgence of unlawful passion, or its scarcely less hurtful influence in legalized unions? This is a question of importance to every one, but, above all, to the medical profession.

CASE OF RADICAL CURE OF HERNIA.

BY A. ADY, M.D.,
MUSCATINE, IOWA.

I was called January 19, 1888, to see C. B., 59 years old, a farmer, who was suffering with a strangulated direct inguinal hernia of the right side, which I succeeded in reducing by taxis, but with difficulty. The patient was an old soldier who had suffered from chronic diarrhœa since 1863. He was partially paralyzed on the right side; complained of palpitation, and in addition his feet were swollen and both lungs emphysematous. His urine was found to be albuminous; and the microscope revealed hyaline and granular casts. I fitted him with a Hubbard truss, but he would not wear it next to the skin, and of course it was not effective.

On February 2, he came to my office with his hernia out again, and was unable to return it; I reduced it by taxis, but with greater difficulty than before. He returned again on the 25th in the same condition, and this time he was suffering pain. A hypodermic injection of half a grain of morphia and one-sixtieth grain of atropia was given him close to the protrusion, and taxis tried, but in vain. He was then sent home, and within an hour I was at the bed-side accompanied by an assistant. After complete anæsthesia with chloroform, effort at reduction was still ineffectual, and we operated at once. The tumor was as large as a quart measure. The sack was adherent to surrounding parts. After reaching the hernial aperture we found that the constriction was within the abdomen at the neck of the sack, which felt like the neck of a bottle or jug. This being incised the reduction was readily made.

The hernial sack was dissected out with the purpose of securing it within the abdominal ring; when doubled up it was found to be rather voluminous. Half of it was then cut off, and the remainder being rolled up was placed in the hernial opening and securely fastened by numerous interrupted

stitches of catgut, extending from the plug to the inner wall of the canal. As an additional precaution the first stitch for closing the wound was passed deeply through the enclosed tissue, closing the rest of the wound with silk suture. A compress wet with biniodide of mercury was bandaged upon the part and left undisturbed four days. The antiseptic used on the sponges, and in the water for washing the incision during the operation, was a solution of hydronaphthol.

The surroundings were not good. The family had to live, eat and cook in one little room, with nothing but a cook stove and green wood to keep up warmth. During the time that we were operating, there was a blizzard blowing, and it was so cold in the house that in spite of towels wet with warm water, the bowel (a portion of the colon) was cold before we could reduce it.

Considering his unfavorable surroundings, persistent chronic diarrhœa, paralysis and albuminuria, we fully expected an unfavorable termination, but instead, his recovery was uninterrupted. The temperature never rose above 99°. In four weeks he was able to come to town, two miles distant from his home, with not the slightest evidence of a return of the hernia.

AMERICAN MEDICAL ASSOCIATION. SECTION WORK.

Second Day, May 9, 1888.

SECTION ON DISEASES OF CHILDREN.

Dr. I. N. Love, of St. Louis, read a paper on

Membranous Croup and Diphtheria: are They Identical?

Since the appearance of Brettoneau's paper, about 1831, our first real and definite knowledge of diphtheria had its beginning, but the question of this paper has not yet been decided. After special clinical opportunities, Dr. Love took a pronounced position that membranous croup and dipththeria are identical. Dermatologists have given half a dozen different terms for erysipelas, yet, as a matter of fact, we know, pathologically speaking, that they are all one and the same disease, dependent upon the same germs and only varying in degree, action or manner of announcement. In fevers the same disposition was manifested, when typhoid fever, plus malaria as a complication, permitted the newly-coined term, typho-malarial. Whether the membrane, as in the so-called true croup, be a fibrinous exudation, superficial and easily stripped from the surface, leaving a smooth mucous surface only robbed of its epithelium, while that of diphtheria is more of a coagulation, penetrating or poured into the mucous tissues—a necrosis as it were, in which the eschar can be removed only with great difficulty—is not important, it being largely dependent upon the anatomical characteristics of the parts involved. That the disease is due to a special germ or microorganism is admitted, and the recognition of this pathological point in the treatment has made a much more favorable showing in the mortality reports. One fact which is worthy of notice, and which is an additional argument in favor of the identity of the two diseases, is that the classical treatment for croup has for years been free exhibition of the mild chloride of mercury, coupled with stimulation, with a view to its defibrinating effect. The secretory system has thus been stimulated, and the effect has been to favor the moistening and exfoliation of the exudation, and antagonize the disposition to constitutional involvement.

Since the same plan of treatment has been applied to general diphtheria, the tendency has been to the securing of a similar result, and the mortality reports present a more favorable showing. By the prompt recognition of the first appearance of diphtheria, and the immediate institution of imperative interference in the shape of free purging with the mild chloride, local antiseptics, rendering the infectious matter innocuous, and the continuance of constitutional measures which are germicides and stimulators of glandular action—first on the list being the bichloride, benzoate of soda, and large quantities of water—we can without doubt claim accomplishments that are tangible and positive.

Dr. Love closed his paper by saying he felt strong in the conviction that croup and diphtheria are one and the same disease, and that the teachings of pathological anatomy, as well as the clinical symptoms, would justify no other conclusion.

SECTION ON DERMATOLOGY AND SYPHILOGRAPHY.

The discussion on

The Limit of the Period during which Syphilis can be Communicated by Contagion or Inheritance

was opened by the reading of a letter from Dr. L. B. Bangs, of New York, in which he said that there was admitted to be a limitation to the contagious period of syphilis, and that this period was important in reference to the question of marriage. Dr. Bangs concludes from an analysis of eighty-seven cases

reported by M. Fournier, that we have absolute proof: First, of the non-contagiousness of syphilitic sequelæ, or so-called lesions of the tertiary stage of syphilis; Second, of the possibility of the spontaneous cure of the contagious stage of syphilis; Third, that the limit of the contagious stage in syphilis may be put within the period of five years. Dr. Jonathan Hutchinson does not think any case of actual contagion can be proven after two years. There is reason to believe, says Dr. Otis, that virus in the blood does not remain potent for contagion after the primary and secondary lesions. No instance is on record of contagion from a tertiary lesion or from one produced more than five years after the primary disease. The period might be shortened to three years.

Neumann thinks it probable that syphilis is caused by micro-organisms. After the disappearance of all the clinical symptoms of syphilis, he has found numerous exudation cells of a round and spindle-shaped form in the skin and mucous membrane. These cells, which were very infectious in the recent stage of syphilis, augmented and proliferated very rapidly. In the recent stage they could infect healthy persons if these were deprived of their epidermis. At a later stage the number of round cells is diminished, and replaced by spindle-shaped cells and connective tissue corpuscles. In the tertiary they grow more slowly. Still later they undergo fatty and caseous degeneration. These round cells are always present in the skin and mucous membrane during the latent stage of the disease, and form a continuous source of infection to the patient. Neumann also found the papillæ enlarged, the walls of the blood-vessels infiltrated with round and spindle cells, and the lymphatics abundant, as long as two or three years after the primary infection.

The question of *reinfection* might throw some light upon this question. That is to say, when a person has so far recovered as to become again infected, we may assume that at the time of the reinfection he was incapable of infecting another person. The author then cites eleven cases of reinfection, the average time elapsing after the primary disease being five years.

Dr. Palmer, of St. Louis, continued the discussion by saying that the question of reinfection had a close bearing upon the subject of marriage. Reinfection in other diseases, such as small-pox, measles, etc., forces us to acknowledge the possibility of reinfection in the case of syphilis. The question is, when can an uncured man marry? Is there a time when syphilis will not infect the wife? He believes we are still unable to differentiate between the times when a man is dangerous to his wife and when he is a syphilitic. In order to decide this question there are laws to be developed. When a man is well treated and obeys his doctor, he may marry in five years. We have this question before us in very many forms, but he does not believe that the current literature and knowledge of the matter are sufficient to establish any rule. The present tendency is to shorten the limit of the prohibition of marriage. If a syphilis germ be found, the spermatozoa cannot convey the disease. It would destroy it.

Dr. Keller spoke of a case he had had in 1877. The patient was sent to the Hot Springs soon after the appearance of the initial sore. Afterwards a constitutional treatment was employed. Despite his physician's protest, the man married in a few months. Some months later mucous patches appeared in the man's mouth. The wife was not infected. She was carefully watched through gestation and was perfectly well. The child was born with snuffles. In four or five days the skin became mottled, and in ten days the mother was spotted all over. The later children were well and the first child recovered.

Dr. Ravogli reported a case in which he knew the father and mother, and neither had syphilis. He had been called to attend the woman and had delivered her of several healthy children. But she later had a child which was sickly at birth. In two days syphilitic sores appeared. Three days later it died. The woman later had another child, (miscarried at eight months); when born the skin was badly macerated. Later, another child was born at nine months, but died. He thought in this case something was wrong with the mother. He referred to another case in which the wife had contracted syphilis from the husband, and where the treatment was unsatisfactory, because she could not be told what her disease was. A child was born and died. She has since had another child, which displayed syphilitic symptoms, which succumbed to mercury, and it is now doing well.

The next paper read was by Dr. Josef Zeisler, of Chicago, on

The Importance of Local Treatment in Syphilis.

There are few diseases for which our therapeutical actions are so well defined as for syphilis, yet when and how to use mercury and iodine is the great difficulty in treating

syphilis. The results of neglecting proper local treatment are often very serious. Although there is nothing especially new to be said upon the subject, yet as the text-books usually treat this question in a rather superficial manner, it may be well to call attention to the subject. Constitutional treatment is not, however, to be underestimated. The local treatment may be successfully employed in nearly every stage of syphilis, but those shown in the tertiary form are of the most importance.

Most physicians use the local treatment only for the primary indurated sore. I do not think that excision at this period can abort the disease, as the induration is a sign of constitutional infection. In the case of hard chancre I have found the mercurial plaster useful in making the induration disappear.

After the secondary symptoms have appeared, local treatment is useful. I prefer inunctions, which, besides their constitutional effect, have an undoubted local influence.

Patients generally desire the visible manifestations to disappear from the face and forehead, and for this purpose a ten to twenty per cent. ointment of the white precipitate is successful. For the papular syphilis on the palms and soles, the so-called psoriasis specifica, chrysarobin has been used from ten to twenty per cent. strength. Sigmund speaks highly of a one to two per cent. solution of sublimate in collodion, painted once or twice daily on the infiltrated places, avoiding the fissured places. Gilles de la Tourette recommended warm baths, with an addition of one part each of sublimate and of chlorate of ammonium to 2,000 parts of water. Papules on mucous membranes will yield to nitrate of silver.

More important are topical applications, for moist papules or condylomata, since these are especial sources of infection. For the removal of those vegetations different caustic pastes have been recommended, but they are very painful. I prefer cauterization with the silver stick, previously anæsthetizing the parts with a strong solution of cocaine.

There is rarely occasion to act against the swelling of lymphatic glands. For suppurating buboes surgical interference is necessary.

During any mercurial treatment the mouth requires attention, as the saliva soon becomes impregnated with the drug and causes mercurial stomatitis. Care of the teeth and gums, abstinence from tobacco and the use of an astringent mouth-wash will delay this. Sometimes it is necessary to suspend the administration of the mercury.

In later stages of the disease, local treatment is imperative, and is regarded by Hutchinson as more important than the constitutional. Iodides will not arrest the destruction caused by the ulcers on the skin and mucous membranes, and here local treatment is followed by the most brilliant results. What has been said of the value of local treatment of the skin applies still more to the eye, nose, throat, larynx, and other organs. When one of these is affected there is no time to wait for the effect of internal treatment.

Dr. Dumesnil, of St. Louis, called attention to the use of nitric acid. In anal and vulvar syphilides, he said, constitutional treatment was not efficient, but the local treatment frequently worked like magic.

Dr. Palmer said that the main thing to do was to look to the cause, rather than this or that particular agent. It was especially important to cut off the moisture on which the continuance of the growth depends. We should select our remedy with this purpose in view.

Dr. Ravogli said that he had good results from iodoform, where the patient can not bear other local treatment. As to the general treatment the great question was, how to introduce the mercury into the system.

The form used was indifferent, as it becomes sublimate. He preferred hypodermic injections, since they do not produce salivation.

Dr. Keller said that he made a special point to instruct the druggist not to furnish an ointment containing any form of petroleum. He found the animal fats far superior to mineral oils as bases of ointments.

Dr. Palmer expressed great satisfaction at what the last speaker had said. He had for the past ten years been studying the difference between mineral and animal fats and had found the animal fats superior.

SECTION ON PRACTICAL MEDICINE, MATERIA MEDICA AND PHYSIOLOGY.

Third Day, May 10.

Dr. I. N. Danforth, of Chicago, read a paper on

Evolution of the Cystic Kidney.

By cystic kidney is meant that condition of the organ in which it is more or less completely converted into a number of cavities, each uniting, containing fluid or semi-fluid matter, and possibly, solid matter as well. The number of these cavities varies greatly, sometimes being limited to half a dozen, or even less, sometimes reaching several hundred. The size of a cystic kidney varies greatly. Sometimes it is not perceptibly enlarged; at other times it is enlarged to three or four times its normal dimensions.

The cause of cystic or sacculated kidney may be classified as follows: 1. Diathetic causes: (a) excess of saline elements of the urine; (b) tuberculosis; (c) carcinoma. 2. Congenital causes: (a) floating kidney with consequent "twist" of ureter; (b) congenital hydronephrosis; (c) congenital degeneration of elements. 3. Mechanical obstruction consequent upon disease of the pelvic organs. 4. Traumatic causes. 5. Pathological cysts: dermoid cysts, hydatids, cystic metamorphosis.

Cystic Kidney Produced by Diathetic Causes.

By far the greater number of cystic or surgical kidneys occur during the active period of life, when the peculiar diatheses which lead to them are most likely to manifest themselves, and this is peculiarly true of the first group of cases—those produced by an excess of the saline element of the urine.

Tuberculous disease of the kidney does not often occur as a primary disease, although those who are much in the dead-houses of our hospitals find occasionally primary specimens, but whether the deposit be primary or secondary its behaviour is substantially the same. The tubercular deposit is most common in the cortex, and generally each deposit clusters around some arterial twig.

In the adult, carcinoma of the kidney is almost never primary, and it is a well-known clinical fact that secondary manifestations of renal cancer are by no means common. Moreover, when secondary cancer of the kidney *does* occur, it is not generally followed by cystic degeneration. Nevertheless, this does occasionally happen, and in the following manner: Cancerous deposits in the kidney sometimes occur as infiltrations, sometimes as round nodular deposits. In the latter case each nodule is surrounded and isolated by a fibrous capsule, composed of hypertrophied connective-tissue. By a certain process the cancerous nodule is gradually shut off from its blood supply, to an extent at least sufficient to induce early and rapid retrograde changes, fatty or mucoid degeneration; hence the solid cancerous nodule becomes transformed into a soft pultaceous mass, or even into a dirty yellow or grayish fluid. This generally finds its way into the pelvis of the kidney, and thence into the bladder. It sometimes happens that the first intimation of renal cancer comes from a profuse discharge of purulent or bloody matter by the urethra, which signalizes the fact that the cancerous nodule has undergone degeneration, and then tunneled its way to the renal pelvis, whence its escape is of course easy.

Primary cancer of the kidney is a disease peculiar to children "before the first or fifth year." It is almost always of the encephaloid type, and sometimes attains immense proportions. He has seen one case in which the cancer distended the abdomen to an almost incredible degree, while the alimentary canal, the liver, and other abdominal organs were compressed and crowded so as to be hardly recognized. In this case there were numerous cystic cavities, with fluid contents of a dirty-gray color, which were probably produced by the breaking down of isolated cancerous masses in the manner set forth.

Cystic kidney produced by congenital causes: migratory kidney with consequent twist or doubling of ureter. He used the term "migratory kidney" advisedly, to include both the movable and floating kidney, their anatomical and pathological relations now being well understood. The liability of the ureter to become twisted or doubled depends very much upon the range of movement which the organ possesses.

General Congenital Cystic Degeneration.

At rare intervals an infant is born, or is delivered instrumentally, with an enormously distended abdomen, due to the fact that the kidney has been converted into a "congeries of cysts" by a process of general cystic degeneration. Such a case is recorded in the *Medical Record* for January 21, 1888, and a few similar cases are on record. They are regarded as a peculiar form of cystic degeneration of the Malpighian bodies, but occasionally the convoluted tubules appear to be involved—in other words, only the functional or potential portion of the kidney seems liable to this form of degeneration, and even then the process probably begins during intra-uterine life.

Cystic disease of the kidney produced by mechanical obstruction consequent upon disease of the pelvic organs: diseases of the bladder; any form of cystic disease which produces thickening of its walls, or intramural infiltration so as to partially occlude the orifices of the ureter, is capable of inducing cystic kidney. The diseases of the bladder most likely to produce cystic kidney are inflammation, carcinoma, sarcoma, and tuberculosis.

He had recently seen a case of double hydronephrosis in a woman of about forty years of age, whereof the only discoverable cause was compression of the ureter by a much enlarged and prolapsed uterus. The

cervix uteri was enormously hypertrophied, tilted up against the bladder, and fixed in this position by adhesions, so that the ureters were constantly, though not very severely, compressed thereby. The consequence was partial retention of urine in the renal pelvis, and the slow but gradual and constant distention of the kidney until nothing of renal structure remained, except a thin layer of cortical structure just beneath the thickened capsule.

Malignant disease of the uterus not infrequently produces cystic distension of the kidney. Tumors of the broad ligament generally cause more or less complete stenosis of the corresponding ureter. Ovarian fibroids have been known to produce the same consequence, and pelvic cellulitis, especially when followed by extensive suppuration, is very likely to be followed by gradual closure of one or both ureters. In short, any pelvic disease which is followed by pathological new formations, or the dislocation of the pelvic organs, may produce compression of the ureters and cystic kidney.

The traumatic causes cannot be formally classified. Any injury of the kidney may result in cystic disease, but *how* and *why* we cannot always explain. As an example, he had seen a short time ago the case of a young man who fell down a rough and precipitous hillside, thereby receiving some injury of the right kidney, which was followed by pain, tenderness and hematuria. These symptoms shortly subsided and the patient regarded himself as quite well, yet the kidney remained slightly tender. He had occasional, but not severe, attacks of nephralgia, and four years after the injury he died after nephrotomy, the kidney being an enormous multiple abscess.

FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

SEVENTEENTH SESSION, AT ORAN, ALGERIA.[1]

(Reported by Arthur C. Hugenschmidt, M.D., Paris.)

Fourth Day, April 2, 1888.

President, Dr. Cros (Oran.)

Multiple Thrombosis.

Dr. Fabriés (Sidi Bel Abbes) treated in November, 1887, a young man 19 years old, suffering with pneumonia, which lasted ten days. On the twelfth day he developed thrombosis of the right crural vein, and a week later the left crural vein was involved. By December 20, all symptoms had disappeared, there only remaining an indurated cord along the course of the vein. On January 10, after a walk, he was taken ill with gastric disturbance, followed by hæmaturia and pain in the region of the right ureter; this disappeared on the fifth day. On the eighth day the trouble recurred on the left side. The urine showed a few fibrinous casts. On January 25 he vomited a large quantity of blood, and had three bloody stools. On February 10 pain in left side and bloody sputa, indicating obliteration of the left pulmonary vein, occurred. All these accidents were without doubt due to a thrombosis of the veins which supplied the different organs involved: obliteration of the renal veins produced a congestion of the kidney, terminating in hæmaturia and albuminuria, which is exactly what occurs when the circulation in the renal vein is arrested experimentally.

Treatment of Idiopathic Hydrocele by Electrolysis.

Dr. Spreafico (Oran) found that the use of electrolysis in the treatment of idiopathic hydrocele was very efficacious. Moreover, the treatment causes very little pain and takes a very short time. No bad effects are to be feared from its employment. He has even employed this treatment in hydrops articuli. Dr. Cros admits that albumin will coagulate on account of the current, but he would like to know how the liquid is absorbed, as he thinks that absorption must be rendered more difficult if the tunica vaginalis is lined with a layer of albumin.

Primary Infectious Orchitis.

Dr. Hublé (Marnaia) has observed for the past five years a series of ten cases of orchitis, which have appeared spontaneously, without any relation to the usual causes, namely, syphilis, gonorrhea and tuberculosis. He ascribes to it the following clinical characters: It usually appears first by a fever of the remittent type; the epididymis is involved at the time when the fever appears, or may be later; the gland itself is sometimes affected, but remains smooth and nearly painless; sometimes slight effusion occurs into the tunica vaginalis. This orchitis is usually accompanied by slight involvement of the joints, with jaundice, purpuric or other eruptions, and sometimes a temporary albuminuria. The average duration is from four to twelve days. Recurrences are observed. The prognosis is not serious; atrophy of the testicle is sometimes observed as a sequel. The

[1] Continued from page 572.

treatment employed is compression of the part with cotton-wool, and quinine and purgatives internally. The causes of this orchitis are probably to be found in the climate, and there are also the individual, general or local causes. He thinks the malarial micro-organisms might have a part in the production of this trouble.

Medical Treatment of Tubercular Patients.

Dr. Verneuil (Paris) always employs medical treatment before he resorts to surgical intervention in tuberculous patients. He puts all his patients previous to operating on a preparatory treatment consisting of one grain of iodoform every day for four weeks, and when the patient has been operated upon, he continues what he calls his post-operative treatment, divided into two parts: the one, which is internal and pharmaceutical, is still iodoform—he resumes it eight days after the operation; the other, the most important one, is emigration. He then proceeded to say:

By emigration, I mean the removal of the patient from the place in which he contracted the disease and in which he has been operated upon; of these places there are two sorts: curative places (mineral springs, etc.), and places where the air is perfectly pure. The two following cases will illustrate.

A young man, 30 years old, had been operated upon before for a coxalgia, with perfect success. He remained with an ankylosis and sub-luxation of the hip-joint. When 27 years old he had irregular pains in that same hip-joint, and soon an abscess formed around the articulation. As I did not like to open the part and scrape it, I sent the young man back to his country home, where the pus was aspirated. He was kept in bed for fifteen days, and the abscess did not reform. He was then compelled for one reason or another, to emigrate to Algeria, and since then he has been in perfect health. My second patient had numerous anal fistulæ, which had troubled him for fourteen years. I operated on this man, and he left the hospital much better, but not quite cured. He also came to Algeria, by chance, and is to-day perfectly cured and in a perfect state of general health.

Gymnastic Treatment of the Period of Asphyxia in Cholera.

Dr. Pauly (Oran) observed during an epidemic of cholera in 1859, that French soldiers, when their comrades were taken with cholera, forced them to walk about, by sustaining them if they were too feeble to walk themselves, and that good results had followed this practice. He applied this treatment in his ambulance during the last epidemic with gratifying results. It cannot be ordered for patients already invalids, who are attacked with cholera, or for very old people; but all other patients ought to be submitted to it. This method is excellent in day time, still more so at night on account of the cool atmosphere, and still better if there is a light rain, for these will stimulate the peripheral circulation which seems to be at fault, and so combat the asphyxic stage. As adjunct to this treatment, friction can be applied to the hands and face of the patient, with a napkin dipped in very cold water, while he is walking about. This walking can take place anywhere in a garden, on a terrace, on a public place, or even in a large room, the windows being wide open.

On the Prognostic Value of Ampullar Dilatations of the Tongue.

Dr. Gillot (Autun) has remarked on the internal surface of the tongue, in the line of small vessels and capillaries, more of less numerous and well developed dilatations, presenting the same structures as miliary cerebral aneurisms. He has found a close relation between these aneurismal dilatations of the tongue and analogous alterations of the cerebral capillaries. These vascular lesions he has found always related to the arthritic diathesis. Their existence lead one to suspect the presence of the same in the cerebral vessels, and can help to make a prognosis in cerebral affections.

Note on a Case of Polydactylism and Syndactylism.

Drs. Seguy and Levy (Algeria) present the mould of a young Jewish girl's hand, bearing seven fingers, including one supplementary ring finger and a little finger, the two ring fingers being united by an interdigital membrane. The skeleton was complete even to the nails; they were both articulated with the corresponding metacarpus. The restoration consisted in the disarticulation of the two fingers. A dry dressing with sawdust and bichloride of mercury was applied.

Convulsive Tic Cured by Hypnotism.

Dr. Burot (Rochefort) has employed this method on a young woman 20 years of age, who for fifteen months had convulsive tremblings of the face, accompanied by the involuntary use of more or less obscene words. The young woman is now cured after one year's moral treatment. This disease, he says, is due to a want of equilibrium between the sphere of intellectual activity and the sphere of cerebral automatism.

Moral gymnastics replace the equilibrium to the advantage of the intellectual sphere.

Rare Form of Spermatic Cyst of the Scrotum.

Dr. Vautrin. The spermatic cysts are said to be scrotal tumors, containing a milky fluid and spermatozoa. I have two cysts from one individual, and find the wall to be composed of a ciliary cylindrical epithelium—a layer of unstriped muscular fibres and a layer of connective tissue. This is the histological constitution of the vas deferens and vasa aberrantia. I concluded that these vasa aberrantia may lose all communication with the vas deferens, and so constitute isolated cysts, containing spermatozoa. Spermatic cysts are formed in the remains of the Wolffian body. For cysts outside the tunica vaginalis the operation is an easy one, but for cysts within the tunica vaginalis the latter must be incised beforehand, which operation he thinks preferable to the injection into it of an irritant liquid. With antiseptic measures we need have no fears of the consequences of the operation.

Dr. Verneuil does not employ incision for the treatment of cysts within the tunica vaginalis, but prefers the injection of iodine, which, he says, nearly always succeeds in these cases.

Fifth Day, April 3.

President, Dr. Cros.

Dr. Trolard (Algeria) read a paper on the Prophylaxis of Hydrophobia, and also one on Naval Quarantine.

Treatment of Mental and Nervous Diseases by Hypnotic Suggestion.

Dr. A. Voisin (Paris) has continued his observations, and has treated a case of melancholia, with hallucinations and suicidal tendency. The disease had lasted two months, and was cured in fifteen days. He has also treated a case of melancholia with agitation and violent impulses. This was cured in two consultations. A hypochondriac, suffering with chronic nervous troubles, which had lasted eight years, and with a beginning paraplegia, was cured in three sittings. A case of dipsomania of ten years standing, associated with melancholia, was cured in the same manner. In insanity with excitement he produced hypnotic sleep. During the catamenial periods he suggests to the patients to sleep from the beginning of their menstrual flow for six or seven days, allowing them to get up only when it is necessary. These cases were cured. Their insanity might have been hysterical or not; the important point, he says, is that they are cured.

Dr. Grasset recommends successive hypnotization, from which most surprising results will be obtained. At the beginning the suggestive power must be concentrated exclusively on sleep. He has himself cured an hysterical paralysis, which had lasted six months.

Extirpation of Deep and Benign Growths from the Soft Parts of the Palm of the Hand.

Dr. Gross (Nancy) presents two cases of this kind.

Case I.—A young man, 25 years old, had a spongy osteoma in the middle of the palm of the hand, behind the flexor tendons of the fingers and in front of the superior extremity of the fourth metacarpal bone. The growth had no connection with the bony skeleton of the hand; it was either an epiphyseal exostosis or a parosteic osteoma of Virchow. Excision was performed by passing between the tendons of the fourth and fifth fingers.

Case II.—Fibroma of the upper portion of the hollow of the hand, in front of the tendons and ulnar artery and nerve. The method of choice for extirpation of the deep tumors of the hand, is the one which consists in reaching the sub-tendinous region by passing between the tendons of the fourth and fifth fingers and the terminal trunks of the median and ulnar nerves.

Amputation of the Leg.

Dr. Duzea (Lyons) read a paper on the preservation of the periosteum of the calcaneum in amputation of the inferior extremity of the leg. Long ago Prof. Ollier, of Lyons, had proposed to save the whole periosteum of the calcaneum in amputation of the lower extremity of the leg, with a large posterior plantar flap. Dr. Duzea thinks that in all such amputations of the leg, a very important matter is to remove completely the calcaneum, but to reserve with the greatest care all the periosteum of the same. The operation is a simple one. The counter opening must be made, of course, as low as possible; the tendo Achillis must be cut and the suture of the extensor tendons of the plantar aponeurosis must be performed; a posterior splint in plaster-of-Paster, curved below and in front, will complete the treatment. This method will protect against hemorrhages, as the principal artery of the flap is not cut, and the nerves and vessels not being injured, will prevent the occurrence of any trophic changes or mortification; in all cases the calcaneal periosteum, which has been preserved, will form a new bone, which will render the stump much stronger.

Dr. Marchand (Paris) thinks this operation an excellent one in traumatic amputations, but he prefers a much more extensive amputation in cases of tubercular lesions.

Dr. Duzea thinks that it is objectionable to keep even diseased periosteum; for Prof. Ollier has long since proved this. He does not, in these cases, look for a primary union; but leaves a drainage-tube in the wound and occasionally injects iodine solution to irritate the surface, and has had no recurrence of the disease.

MISSOURI STATE MEDICAL ASSOCIATION.

THIRTY-FIRST ANNUAL SESSION, HELD AT KANSAS CITY.

April 17, 18 and 19, 1888.

The meeting was called to order promptly by Dr. F. J. Lutz, of St. Louis. The Association was welcomed in an address by Mayor Kumpf, of Kansas City.

Investigations throughout the State concerning Phthisis Pulmonalis

was the subject of the remarks by Dr. B. F. Host, of Brownsville. He found that pulmonary consumption was not on the increase. He found it not so prevalent here as in the older countries of Europe where population was denser. He thought it contagious, but not in the same manner as disease is usually considered contagious. He deplored the wonderful ignorance of the danger of the disease among the old and the young, and hoped that knowledge would be disseminated among the people concerning this disease. He thought many errors were made on the part of physicians, especially in sending patients to other climates, and that at least six months should be taken in passing from a low to a high altitude.

Practical Points in Railroad Surgery

was the subject of a paper by Dr. Willis P. King, of Sedalia, who explained the pain which occurs in lacerated wounds by the necrosis of the soft parts, the contact of the dead and dying with the living tissues. In proof of this he cited the fact of the disappearance of the pain when the diseased tissue was removed. He preferred a secondary operation in amputations of the lower extremities. In railroad injuries where there is much crushing he was inclined to favor the cutting away the crushed parts, dressing the limb antiseptically and waiting for the absorption of effused blood and the return of the normal condition of affairs before doing an amputation. In amputating between the ankle and the knee-joint he makes a flap amputation which is of his own design, and which will be known as the King's flap. He makes the entire flap from the posterior part of the leg, and removes the soft parts anteriorly from one to two inches above the point at which the bone is divided. This is especially suitable at a secondary operation, when the injury has been mainly on the anterior part of the leg. The object of the flap is to throw the line of the cicatrix above and to the side. In operations about the feet, when it is necessary to go further back than the tarso-metatarsal joint, he favors sub-astragaloid disarticulation. He employed scissors in place of the knife in exsecting in this operation. They facilitate the operation very much, and make a much nicer result. He uses straight scissors on the sides and bottom and curved scissors behind. He laid great stress on the use of scissors. In all operations he urged the strictest application of antiseptics. He thought them of possibly even greater benefit in crushed injuries than in others, for the reason that crushed wounds are ten times as apt to have septic infection as others. Immediately after the time of injury a person is in the most imminent danger of septic infection.

The State Board of Health

was the subject of a paper by Dr. George Homans, of St. Louis, who is Secretary of the Board. It is much crippled for want of means, but is doing some good in restricting practice to those legally qualified.

Gynecology, Testicology, and Comparative Sterility in the Male and the Female

was the subject of a paper embodying the report of several interesting cases by Dr. Edward Borck, of St. Louis. The progress in the treatment of gynecological affections he thought had been wonderful and the cures so remarkable, that the present generation will be entirely free from suffering before long. From the latest returns it is safe to say that nine women out of every ten have some tilting up or sinking down of their organs, or the opening of the uterus is too large or too small. Why have women, or rather their sexual apparatus received so much attention from medical and other men? Is it because we all love women so much that we are wholly absorbed in the welfare of their reproductive organs? The diseases of the testicle receive little attention. New works are not springing up on

every side. Are the ovaries in women not generally considered the analogue of the testes in men? The profession has given to the former organs the kindest attention possible; to the latter almost none. If only one man in ten is affected with a disease of the testes, what a rich field for study and inquiry for the testicologist. Women suffer from neuralgic pain in the ovaries, and men suffer from neuralgic pain in the testes. When all known remedies fail, woman cheerfully gives up her ovaries; but it is not so with man. He suffers and suffers, and in some cases lands in the insane asylum, and takes his testes with him. Yet the removal of the testes is not nearly so dangerous an operation as the removal of the ovaries. The author was a strong advocate of specialties in medicine, and believed in specialists; but he did not believe that every new graduate should rush off to Europe at once to study a specialty and after three months return a full-grown specialist. Such a man has one-sided ideas unless he does his share of general practice first.

The author then reported a number of cases illustrating his remarks; one of which was that of a healthy young woman whose husband was apparently well, and yet who after four years had no children. The family physician exhausted himself, then turned the case over to a gynecologist, who discovered at once the least bit of tilting of the womb. Every time the woman visited him, he told her she was growing better. But the woman did not agree with him, and at last in a state bordering on insanity she was turned over to a neurologist, who said her nervous system was out of order—and by this time it certainly was. The neurologist failed, however, to cure her, and she came into the hands of the speaker. He found the diagnosis of his predecessors correct, but he could not consider either the woman's womb or her nerves the cause of her sterility. He therefore sent for her husband, and found that he suffered from fatty degeneration of the heart, and had fatty deposits in the scrotum and testicles, and fatty degeneration of the spermatozoa. Temporary separation from his wife was advised, and after six months' absence in Europe he returned and in due time a boy baby was born. In another pair, of which the wife was treated for sterility and the husband for brain trouble, examination showed a left testicle hypertrophied from epididymitis. After removal of the offending organ, his wife in due time gave birth to a child. Two other such cases were reported.

Sympathetic Affections of the Eye Viewed from a Modern Standpoint

was the subject discussed by Dr. Adolph Alt, of St. Louis. He was of the opinion that sympathetic affections of the eye should be as well known to the general as to the special practitioner. Eyes which have suffered a perforating injury are most apt to cause sympathetic trouble. Of this affection there are two kinds: irritation and inflammation. All sympathetic troubles unless treated soon enough lead to total blindness. A direct inflammation of one eye can take place from the other through the optic nerve. To prevent the disease he recommended the removal of the injured eye.

The First Care of the Injured

was discussed by Dr. A. H. Meisenbach, of St. Louis. He thought that railroad men should receive instruction in rendering first aid to the injured. There was thousands of cases in which a little knowledge would be of inestimable value.

Leprosy, with a Report of a Case

was the subject of a paper by A. H. Ohmann-Dumesnil, of St. Louis. This case was said to be the first one ever observed in St. Louis.

The Election of Officers

resulted as follows: *President*, A. W. McAllister, of Columbia; *Vice-Presidents*, J. D. Griffith, of Kansas City, J. H. Britts, of Clinton, W. A. Camp, of Springfield, H. C. Dalton, of St. Louis, and J. B. Winn, of Macon; *Secretaries*, J. C. Mulhall, of St. Louis, and J. H. Duncan, of Kansas City; *Recording Secretary*, L. I. Mathews, of Kansas City; *Treasurer*, C. A. Thompson, of Jefferson City. Springfield was chosen as the next place of meeting. At the present meeting there were 269 members enrolled—the highest number ever reached.

—At a meeting of citizens, in Association Hall, Philadelphia, May 9, under the auspices of the City Parks Association, the necessity of more small parks for breathing spaces was advocated, and a memorial urging the passage by Councils of the ordinance to establish at once seven of the twenty-one parks proposed was approved. Several well known physicians spoke of the importance of such parks to the healthfulness of the city, and Professor Rothrock urged the necessity for a botanic garden. A letter was read from Dr. Isaac Norris containing a resolution passed by the College of Physicians of Philadelphia, warmly approving the objects of the Association.

Foreign Correspondence.

Letter from Berlin.

Berlin, April 6, 1888.

In the Dermatological Society of Berlin, Dr. Isaac, Dr. Lassar's assistant, has recently showed a rare case of lichen-ruber occurring in a child only fifteen months old. This disease, described by Hebra, usually appears between the age of ten and forty years. Dr. Isaac says that only two cases of such young children have been reported in medical literature. Dr. Lassar believes lichen-ruber to be infectious and that it is frequently to be found in people occupied in the preparation of articles of leather. The case mentioned above confirms this opinion of Dr. Lassar, as the child often played with a shoemaker.

In one of the last meetings of the Medical Society of Berlin, Dr. Behrend described a new remedy for skin diseases, called anthrarobin. Professor Liebermann, of this city, discovered this chemical compound. Dr. Behrend thinks this new remedy can be applied for all skin diseases which have been heretofore treated with chrysarobin; for instance, psoriasis and tinea tonsuraus. Psoriasis is healed by the application of chrysarobin more promptly than by that of anthrarobin. The latter is, however, sometimes to be preferred on account of its not being so irritating. This is especially true in cases of psoriasis of the eye-lids, or near to the same, since it is possible to cause inflammation of the eye by using the former. Dr. Behrend highly recommends anthrarobin in cases of tinea tonsurans. All the cases of this disease which he has treated with anthrarobin have recovered, and he has never seen any marked inflammation of the skin arising from the application of this remedy. In regard to the method of using anthrarobin, Dr. Behrend recommends applying the tincture and not an ointment.

In referring to some passages which are to be found in a very interesting medical pamphlet of Dr. Leopold Casper (Beiträge zur Pathologie and Therapie der Harnröhrenstricturen, *Berliner klinische Wochenschrift*, 1888, No. 11) I call your attention to the following: With regard to liability to the formation of the stricture of the urethra, it is just the same whether the gonorrhœa has been infectious or not. Simple traumatic gonorrhœa may lead to a stricture if the inflammation attacks the deeper layers of the mucous membrane. With reference to the diagnosis, Dr. Casper recommends the use of Leiter's endoscope in some difficult cases in which the seat of the disease is in front of the bulbous portion of the urethra. As to the treatment of the stricture, Dr. Casper is of the opinion that dilatation is sufficient in ninety per cent. of such cases, and that a bloody operation is seldom necessary.

During the month of March two new *cheap* bathing-places for the working-class, have been opened in Berlin. They have been established by a society whose main object is to offer cheap baths to the poor people of Berlin. Our working class here is as a rule, extremely cleanly, both in regard to their clothing and their person. However, the number of warm baths is, taking all in all, too few in comparison with the population, and likewise the prices of the same are too high to allow the working men to make use of them. The fact has been announced by Dr. Oscar Lassar, of Berlin, that instead of there being a warm bathing-place for each thousand inhabitants in Germany, there is only one for each thirty thousand. Through the untiring interest and the energetic efforts of Dr. Lassar an inquiry with regard to the matter has been made throughout Germany. At the Hygienic Exhibition of 1883, the attention of the friends of the poor was drawn to a small bathing establishment in which shower-baths with soap and a towel were given for two and one-half cents. It was likewise the work of Dr. Lassar. In a closed compartment the whole body can be soaped over, and then the soap rinsed off by means of the shower-bath, which first of all pours down warm water, and then becomes gradually colder. Everywhere, bathing establishments according to the system of Dr. Lassar could be erected and kept in working order, for instance in manufactories, schools, barracks, asylums, etc. For the present, here in Berlin shower-baths are combined with sitz baths. These baths are being greatly frequented by the working-class, proving how great the demand for them is. It is a matter for congratulation that a physician has not only noticed the necessity for such baths, but has likewise been able to propose the proper method of putting them into successful operation. Everywhere in Germany, and also abroad, thanks to the kind efforts of Dr. Lassar, the working-class will, before long, have the opportunity of getting cheap warm baths. In this thing alone the science of hygiene has made a rapid onward stride.

Albert Moll, M.D.

Periscope.

Selection of a Climate for Patients with Pulmonary Tuberculosis.

Dr. Frederick I. Knight, in a paper read before the Boston Society for Medical observation, March 5, 1888, gave the result of his twenty years' experience in the selection of a climate for patients with pulmonary tuberculosis. After some remarks upon the main facts which should guide the physician in recommending a change of climate, Dr. Knight gave the following as the principal types of the disease, with the indications of each as to change of climate.

(1) Those presenting the earliest physical signs of tuberculosis of the apex; who have as yet shown little, if any, general disturbance from the disease, and who complain only of morning cough and expectoration. Threatened cases of hereditary disease, in which there are as yet no morbid physical signs, and not much constitutional disturbance, may usually be considered with this class.

It is, perhaps, not saying too much to say that the prognosis has been changed as regards this class of cases from very bad to very good. While he has had such patients do well in different climates, some of them without leaving home, the results have averaged far better, in his experience, in those who have sought mountain climate than in those who have pursued any other course. The region which he has found best for this kind of treatment is the eastern slope of the Rocky Mountains, in the States of Colorado and New Mexico, where the altitude ranges from 4,000 feet to 8,000 feet.

The question, he says, will naturally be asked whether the patient should go at once from the sea-board to such a high elevation, or make a number of stops on his way out, in order to become accustomed to the diminished pressure. He has never known any ill effect in patients of this class from making the change at once; but it is especially necessary that they should consult a good local medical adviser at once, that they may be guided from the beginning, especially in regard to the kind and amount of physical exercise which they should take.

(2) Patients with more advanced disease, showing some consolidation, but no excavation, nor any serious constitutional disturbance. The mountain climate, he says, is suited to many of this class also, and it is fortunate if they are in condition to try it, but if a considerable area of one lung, or the apices of both, are consolidated, and there is well-marked constitutional disturbance, if the pulse and temperature are both constantly above 100, then it may be well to try some low altitude first. For very low elevations, the dry, rather stimulating air of Aiken and its vicinity, or the pine regions of Southern Georgia, may be recommended for the greater part of the year, the patient going north in the summer. When quiescence in the morbid processes is established a move to the higher altitudes should be made.

(3) Hemorrhagic cases, that is, patients in whom pulmonary hemorrhage has been perhaps the earliest, and a frequently recurring symptom, but in whom there is as yet no marked febrile reaction, nor much physical evidence of disease.

This class, he says, seems especially suited to the high altitude treatment. Contrary to the old idea, these patients appear to be less liable to hæmoptysis in high altitudes than on the plains. He usually advises such patients to make several stops on their journey upward, but does not think this precaution often necessary. What he says in this connection is not meant to refer in any way to the hæmoptysis from rupture of a large vessel in a cavity of advanced disease.

(4) Cases of advanced disease, those with cavities or severe hectic symptoms. Patients of this class, he says, had better, as a rule, stay at home; certainly, if they are sick enough to be confined to the house. They can usually be made much more comfortable in their own homes than at any health resort; yet he has sometimes advised that such a patient with very constant and harassing cough be sent to the moist climate of Florida, and the relief to the cough has more than compensated for the want of some home comforts. A poor patient, or one without abundant means even, should not, he says, be given such advice.

(5) Patients in an acute condition. These may be quite different in their nature and requirements. We find, he says, (*a*) cases of acute general infiltration. These patients should be kept at home definitely. (*b*) Cases which begin violently with high fever and marked consolidation of lung, resembling pneumonia. Patients of this class should be kept at home till after the subsidence of the acute symptoms, and then may be removed to some low, dry place; afterward increasing elevations may be carefully tried. (*c*) Cases of acute exacerbation during the progress of chronic disease. Patients of this class should remain at home during the acute stage, going perhaps, to some mild, sedative climate dur-

ing its decline; but as soon as possible after the febrile disturbance is well over, if their condition otherwise warrants it, they should go to an elevated region.

(6) Cases of so-called fibroid or interstitial pneumonia.

Special indications in these cases have to be considered. If the patient is young, and the heart is not enlarged, he may be sent to high elevations. If he is over fifty years of age, or if his heart is dilated, or if his cough is very harassing, a lower altitude should be chosen. Southern California offers excellent places for such, with varying elevation and moisture to suit individual symptoms.

(7) Patients recovering from acute pleurisy or pneumonia, in whom the eruption of tubercle is feared. High elevations is the place *par excellence* for these. The increased respiratory, and consequent increased nutritive activity are exactly what is wanted to prevent the development of chronic disease.

(8) Patients in whom the tubercular process has seriously invaded the larynx.

Such patients he says, should be recommended mild, and even moist climates, and on no account be sent to high altitudes. Southern California he thinks answers the purpose well. The dry air of high altitudes, however, much good it may do by stimulating general nutrition, usually proves so great a local irritant to the larynx that incessant cough ensues, or, if the disease is situated high in the larynx, the swelling and ulceration of the cartilages are aggravated so that severe dysphagia and insufficient nourishment ensues.

(9) Those with complications of other diseases.

In regard to these, he says, a good deal of care has to be exercised oftentimes. In cases of cardiac affection it may be said, that while marked dilatation should prevent a patient's being sent into a high altitude, it is not necessary to exclude every one from such who has a cardiac murmur, or who even is known to have organic valvular disease, with moderate hypertrophy; but such patients should be carefully watched and regulated in their habits, and should not be sent into the very highest altitudes.

In regard to renal disease, while it is admitted by the resident physicians that *acute* nephritis is severe in high altitudes, they do not admit that patients with chronic disease are made worse, but claim rather that they are benefited by a residence there.

Patients with intestinal ulceration are said to do badly in high altitudes, but they do badly everywhere.

In regard to the rheumatic diathesis, it may be said that acute rheumatism is thought to be rather prevalent and severe in high altitudes, and such a tendency might turn the balance in favor of a lower resort. On the other hand, the chronic form of rheumatism does not seem to be made worse by elevation. —*Boston Med. and Surg. Journal*, April 5, 1888.

Cerebral Symptoms in the Pneumonia of Children.

Dr. L. Emmett Holt, Attending Physician to the New York Infant Asylum, in a paper read before the New York County Medical Society, March 26, 1888, discussed the Cerebral Symptoms in the Pneumonia of Children. His paper was based upon an analysis of 173 cases, which were divided as follows:

Seventy-three were lobar pneumonia, with two deaths; and one hundred, broncho-pneumonia, with a mortality of thirty-four. The sexes in broncho-pneumonia were nearly equal; while in lobar pneumonia the males predominated, forty-three to thirty. As to age, one hundred and twenty-three patients, he says, were two years of age or under, and only thirteen were over five years of age. Thirty-four cases, or twenty per cent. of the whole number, presented decided cerebral symptoms. These were divided into three groups: Those attended by convulsions, of which there were fourteen; those in which delirium was the principal symptom, twelve in number; and the third class, in which neither convulsions nor delirium existed, but other symptoms decidedly cerebral in type—of these there were eight cases.

He concludes his paper with the following deductions:

"1. Cerebral symptoms in the pneumonia of children are very common.

"2. Convulsions belong almost without exception to infancy, being rarely met with after two years. Occurring at the onset, they belong essentially to lobar pneumonia; they do not indicate a bad prognosis, nor even, in most cases, a severe attack. When late convulsions come on, death within twenty-four hours may confidently be predicted.

"3. Delirium comes oftenest between the ages of five and eight, usually in conjunction with extensive disease and high temperature. These cases, although severe, with but few exceptions, recover.

"4. There is no such intimate association between certain symptoms and apex disease as has been frequently stated. Such symptoms occur in only about one fifth of the apex cases.

"5. Nervous symptoms occur much more frequently (one-third of the cases), when the disease is extensive and the temperature very high.

"It was not my purpose to enter into the subject of the treatment of these symptoms in pneumonia, as I have nothing new to contribute. I wish to emphasize two points which my experience has taught me. The first is that in hyperpyrexia the cold pack is safe; and the most efficient means to reduce the temperature and thus abate the brain-symptoms dependent upon it. The second is the use of antipyrine, not so much for reducing very high temperature—for I think the cold packs are safer than very large doses, and altogether more satisfactory—but to allay restlessness, quiet delirium and cough, and promote sleep. For this purpose, doses of two or three grains are sufficient in an infant of from six to nine months, and double the dose at eighteen months or two years. The dose may be repeated every six or eight hours."—*Medical Record*, April 7, 1888.

Treatment of Chronic Pyelitis.

In the *American Journal Medical Sciences*, March and April, 1888, Dr. Nathan Bozeman, of New York, publishes an article on chronic pyelitis successfully treated by kolpo-uretero-cystotomy, irrigation of the pelvis of the kidney, and intra-vaginal drainage. He has used the method successfully in two cases. In the first, drainage was provided for by a large urinary fistula; in the second, kolpo-uretero-cystotomy was done to provide drainage and allow of catheterization of the ureters. The evils of incontinence of urine were prevented by using the author's intra-vaginal drainage apparatus. The renal pelvis was irrigated through a French catheter, passed up the ureter. Bozeman has also devised a flexible metallic sound for exploring the ureter; by this calculi can be more easily felt. When treatment was begun in the second case, the renal pelvis held twenty-one drachms, but the capacity diminished to five drachms while under treatment. This is considered the normal capacity. Acute pyelitis was several times induced by the passage of too large an instrument, by allowing the catheter to remain in situ longer than twenty-four hours, and by deficient antisepsis. The fistula was closed after about seven months, by the author's button-interrupted suture. By using the author's intra-vaginal drainage apparatus during much of the time the patient was under treatment she was enabled to perform her daily duties and enjoy the pleasures of life.

Bozeman considers that an artificial fistula at one of the ureteral angles of the trigone of the bladder, furnishes an opportunity for the observation and clinical study of diseases of the bladder, ureters, pelvis and kidneys afforded by no other means. He has not been able to catheterize the ureters free-hand; and condemns catheterization through the dilated urethra, since dilatation sometimes results in permanent incontinence of urine. Not only is catheterization facilitated by the formation of a fistula, but by no other method is vesical drainage afforded; nor would it be practicable to irrigate the renal pelvis daily for a protracted period, except through a fistula. Physiological rest and perfect drainage of the bladder, ureters and pelvis, afforded by this method of treatment, tend to cause the subsidence of inflammation of their lining membrane and atrophy of their thickened muscular coats. In consequence of the removal of the pressure of the urine, an enlarged bladder or a dilated pelvis returns to its normal size.

This method of exploration and treatment is likewise useful, not only in ascertaining the indications for nephrotomy and nephrectomy, but, when employed early, by curing the conditions, which, when neglected, lead to extensive renal disease, in lessening the number of cases in which these grave operations are necessary. Congenital absence of one kidney, coincident disease of both, and pyelitis on both sides, are contra-indications to the performance of the operation of nephrectomy, but not to the employment of this method of treatment.

The use of intra-vaginal drainage in preventing the evil consequences of incontinence of urine, perfects the method by removing the chief objection to its employment.

Nervous Symptoms arising from Displacements of the Uterus and its Appendages.

Dr. Grace Peckham, in a communication on this subject to the *Medical Record*, Feb. 18, 1888, concludes as follows:

From an inspection of these cases, as well as looking through the very many others which were not sufficiently typical to come under classification, the following deductions have been made:

1. Nervous disturbance outside of the pelvis is not nearly as frequent in disease of the uterus and its appendages as is generally believed. The impression that one severe case makes effaces that of dozens of simpler ones.

Moreover, gynecologists who are men, are apt to meet only the severer cases, since women suffer long and in silence before undertaking a treatment which does such violence to their natural modesty. The eminent specialists who have done most of the writing on this subject encounter the most severe and difficult cases, and their object, often, in writing, is to present peculiar and extraordinary cases.

2. It has been shown that mere mechanical displacements give rise to almost no disturbance in complete prolapsus. In the other degrees of prolapsus the pain comes from the pulling and stretching of the tissues. Retroflexion occasions the most nervous disturbance outside of the pelvis.

3. It can be seen that the amount of disturbance is in every way proportioned to the amount of uterine tissue involved, and the length of time the disease has continued.

4. It is plainly shown that the reflex nervous symptoms are no more severe nor extensive that arise from diplacements and inflammatory conditions of the uterus and its appendages than would be produced by pathological conditions of the same extent and the same chronic character in other parts of the body. When these are present a previous neuropathic tendency, either acquired or inherited, probably has existed, and the uterine trouble is generally extensive and of an aggravated nature, which, acting on the central nervous system, produces a display of disturbed innervation at the periphery, or of disturbed cerebration, which results in neuralgias or hysterias.

5. In these studies the effects of uterine trouble upon the eyes have been carefully considered. Three cases, two of endometritis and one of inflammation of the broad ligaments, are found. I have met others, but in these, and looking over the literature, I have reached the conclusion that the eye-trouble is generally due to anæmia and general asthenia, and it is doubtful if it can be proven that such troubles with the eyes occur more often in uterine diseases than in others which would produce a similar state of anæmia and depression of the general bodily strength.

6. Many nervous symptoms are not present *because* of uterine disease, but are due to the constipation and anæmia with which it is so often accompanied.

7. Nervous disturbances outside of the pelvis are much more prevalent among the more highly organized women of the higher classes than among those of the lower, who have less time to think of themselves, and much less vivid imaginations.

8. The attention should be called to the fact that sacral neuralgia often simulates uterine disease; the pain is very much like that described in many of the inflammatory conditions with displacement, and even with ovarian trouble. It is often associated with pain extending down the leg, and pain referred to the sides and the back, and it is also accompanied with general nervousness. I recall, now, three cases of sacral neuralgia in which the nerves were tender at their exit on the right side, and the great pain complained of was on the left side.

Absorption and Excretion of Antipyrine.

Dr. A. Mossella (*Gazzetta degli Ospitali*, No. 73, 1887), has employed antipyrine by the mouth, by the rectum, as an ointment, and hypodermically, and has followed up the excretion of it from the body. After the use of clysters (four parts of antipyrine dissolved in one hundred of water), the temperature fell and excretion of antipyrine by the urine occurred. When employed externally, by means of painting with glycerine solutions, inunctions of solutions in almond oil into the arm and knee-joint, etc., no kind of absorption took place. After hypodermic injection into rabbits (one and a half to one and three-quarter grains at a dose) antipyrine could be very quickly detected in the urine. On the other hand, after internal employment of the drug in pathological conditions, he was not successful in finding it in the sputum, pleuritic exudate, or echinococcus cysts. Excretion through the saliva, the skin or the mammary glands could never be observed. Excretion seems to take place only through the urine.—*Deutsche Medizinal-Zeitung*, March 26, 1888.

Action of Calomel Upon the Bile and as an Intestinal Disinfectant.

J. Sawadsky has proved (*Wratsch.*, 1887, p. 17), that calomel possesses a disinfectant action, which results from its transformation into an oxide of mercury under the influence of the alkalies of the bile in the intestine. The coloration of the stools after the ingestion of calomel should be attributed to the biliverdin in excess, which is liberated during this phenomenon of oxidation. This biliverdin is not altered on account of the antiseptic action of the oxide of mercury. These are the reasons why, after the administration of calomel, the reactions of this salt cannot be obtained from the intestinal contents.—*Gazette Hebdomadaire*, March 2, 1888.

Treatment of the Umbilical Cord.

Dr. A. Jacobi, Clinical professor of the Diseases of Children in the College of Physicians and Surgeons, New York, gives the following advice with reference to the treatment of the cord:

"If the ligature be thin, it is liable to cut through the walls of the blood-vessels prematurely; if too thick, it may not suffice to compress them satisfactorily. It ought to be applied at a distance of from one and a half to two and a half inches from the abdominal wall. Not nearer, in order to avoid the effect of the immense muscular power of the umbilical arteries inside the abdominal cavity. A second ligature is placed about an inch from the first, and the cord cut between them. It is a good rule, which must surely be adhered to in every case of thick cord, to apply an additional ligature between the first and the abdominal wall, to avoid hemorrhage from the insufficiently compressed arteries, which may take place after the cord has commenced to shrink. The abdominal end of the cord is then wrapped up in a dry and soft piece of linen, lint, or cotton, placed on the left side of the abdomen, and fastened, by means of a soft flannel bandage, which is wide enough to cover the larger part of the chest and all of the abdomen, so as not to slip.

In wrapping up the end of the cord no oil must be used. Warmth and dryness favor mumification; moisture and exclusion of air, gangrene. This holds good also for the cord when it is separated from the living baby by an additional ligature, and in the dead. Thus, the former forensic axiom, that a dry cord proved life, which prevailed for decades after Meckel had demonstrated its fallacy as early as 1853, is absolutely worthless. Thus, fatty substances, and moisture of any kind, must be avoided as much as possible. Powdered subnitrate of bismuth or oxide of zinc, or iodoform, or salicylic acid, one part with ten parts of starch, may be dusted round the insertion of the cord and over the stump daily. The latter application is not necessarily useless (from the point of view of antisepsis), for the separation of the cord is a gradual one, and not uniform through the whole thickness of the amnion and the three blood-vessels.

The size of sore stump and the rapidity or slowness of cicatrization depend upon the thickness of the cord, the intensity of the line of demarcation, and the reactive inflammation. The latter are most marked in vigorous infants. As a rule, the surface is dry a few days after the falling of the cord, and cicatrization complete within twelve or fifteen days after birth. This normal process is, however, disturbed by careless handling, local irritation, and infectious influences. In these cases there is a serous or purulent secretion, and cicatrization may be deferred for many weeks. Under these circumstances local treatment is required. Carbolic acid ought to be avoided, for the newly-born infant is easily influenced by its poisonous properties. Solutions of lead, zinc, or alum answer quite well. As before, however, I recommend the powders of zinc oxide, bismuth subnitrate, alum with starch, salicylic acid with starch, or iodoform. Such measures will always prove helpful; to omit them in times of erysipelas or diphtheria is unpardonable. Perchloride of iron, or subsulphate of iron, must not be used. Under the hard coagulation formed by its application over the whole wound secretions will accumulate, cannot escape, are absorbed, and produce sepsis. I have seen babies die from applications of iron to the umbilical stump, as I know of women dying for the same reason when the hemorrhages from their uteri or from the lacerated vaginæ were maltreated in the same manner."—*Archives of Pediatrics*, April, 1888.

Specimens of a Case of Oxalic Acid Poisoning.

At the meeting of the Berlin Medical Society, April 11, 1888, F. Strassman presented the specimens from a case of oxalic acid poisoning which exhibited the characteristic lesions with unusual clearness. They were obtained from a man who had hanged himself, and whose body was being dissected; nothing was known of the poisoning. On opening the abdomen, the stomach at once caught the eye through its gray translucent appearance—a condition to which Liman first directed attention, and which led to a probable diagnosis of oxalic acid poisoning. The throat and œsophagus were eaten away, and in the stomach was found a grayish black, greasy mass; the mucous membrane of the stomach was almost entirely wanting. The acid was diffused and had changed the neighboring organs, as is usual when the poison has had time to act. Even the aorta was eaten away and the blood in it compressed into a hard woodeny cylinder. Among twenty-four cases of oxalic acid poisoning Strassman can call to mind none with such far-reaching effects. In the tubules of the kidney were found numerous crystals of oxalate of lime.—*Deutsche med. Wochenschrift*, April 19, 1888.

Case of Optic Atrophy Following Chorea.

Mr. W. G. Sym reports the following case in the *Edinburgh Med. Journal*, March, 1888, and remarks that the case appears interesting, as bearing to a certain extent upon the question of the pathology of chorea.

"G. S., a boy, aged 17, came to the Eye Wards, Royal Infirmary, on 11th of July, complaining of loss of sight in the right eye. His history was as follows: Up till ten years ago he had perfect vision in both eyes; he then, at the age of 7 years, was seized with an attack of chorea, apparently not of a very severe character, on account of which he was admitted to the Infirmary as an in-patient, under the care of the late Professor Sanders. From this affection he made a good recovery, until one morning he felt a sudden mist, as he expressed it, come over the right eye. At the time when this occurred he was not unduly exerting himself, but merely walking quietly down the ward. From that time he has never seen anything with the right eye. He never received any severe blow or other injury in the neighborhood of the eye. In the family history there is nothing particularly worthy of notice. Neither parent is rheumatic, but one brother, a soldier, is said to have suffered from articular rheumatism.

Examination elicited the following facts: Vision—left eye, $\frac{20}{20}$. Right eye, *nil.* No perception of light. When he endeavors to fix a very near object, the right eye does not converge. Right pupil does not contract to light, but does so in sympathy with the left. Tension normal. On examination by the ophthalmoscope, the right eye presented a condition of absolute atrophy of the optic nerve, the disc being of a dead-white color. The blood-vessels, especially the arteries, were extremely small. There were no traces of hemorrhage or exudation, and the disc, in which the cupping of optic atrophy was well-marked, was normally regular in outline. The macula presented nothing unnatural. The choroid coat appeared healthy, and there was no staphyloma. The left eye was perfectly normal in appearance. There were evidences of slight stenosis of the mitral valve—a presystolic mitral murmur being present, and a reduplicated second sound.

Relying on the symptoms and appearances, and on the very clear and emphatic history given by an intelligent patient, I think one is justified in coming to the conclusion that in this case atrophy of the right optic nerve was due to an embolus plugging the arteria centralis retinæ of that side, and thus cutting off the blood supply from the retina, this having occurred during the attack of chorea, at the moment when he felt the sudden mist over the eye. Those which in other cases of optic atrophy are the more usual causes are in this case much more improbable. Simple atrophy, or atrophy following neuritis, almost invariably affects both eyes, though one nerve may be in a considerably more advanced stage of wasting than the other. But here we have a case of absolute atrophy in one eye associated with a normal condition of the other. In children even bilateral simple atrophy is rare, and so also is neuritis, unless dependent on some gross brain lesion.

It is scarcely necessary to indicate the relation which such a case bears to the embolic theory of the pathology of chorea; the accident is, however, a very rare one. Dr. Gowers, in his *Medical Ophthalmoscopy*, states that there are on record only two cases of embolism of the central retinal artery occurring in consequence of chorea; but Dr. Argyll Robertson informs me that a few years ago he saw a precisely similar case—that of a young lady, in whom atrophy of one optic nerve succeeded a severe attack of chorea."

Pregnancy after Ovariotomy.

The Liverpool correspondent of the *Lancet*, March 10, 1888, reports the following unique case. The patient gave birth to her last child in July, 1882, being at that time thirty-five years old. She did not nurse this child. Shortly afterwards, menstruation became irregular, and finally ceased towards the end of 1884, when a small ovarian tumor was discovered. No operation was then recommended, as the tumor was small and movable. She was, however, kept under observation until February, 1887, when the removal of the tumor was considered advisable, and it was accomplished on February 18. A sarcoma of the right ovary was removed. The left ovary, was examined and found to be small, ivory white and indurated, and no suspicion existed in the minds of those who were present that it contained any more ova to mature. It was returned after the examination. Exactly a month after the operation (March 10), the patient menstruated for the first time in nearly three years, and continued to do so regularly on the 18th of each month until August, when she ceased, and symptoms of pregnancy soon after made their appearance. The pregnancy was verified about the end of the fifth month, and up to the present time has run a perfectly normal course, the patient being in excellent health.

—Dom Pedro, Emperor of Brazil, is reported to be dying at Milan, Italy.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

TREATMENT OF ACUTE RHEUMATISM WITH SALICYLATES.

In an article in the *Lancet*, April 14, 1888, Dr. Donald W. C. Hood, physician to the West London Hospital, discusses the treatment of acute rheumatism, with special reference to the use of the salicylates. The paper is based upon a study of over two thousand cases of acute sthenic rheumatism occurring in persons of both sexes, and under thirty-six years of age. The author analyzes this large number of cases in order to demonstrate the comparative results in the case of patients treated specifically, that is to say, with the salicylates, and those treated on general principles.

With reference to the pain due to joint effusion, Dr. Hood thinks there can be no doubt that in many cases patients treated with salicylates experience a marked and rapid diminution or total cessation of pain, and coincidently with this loss of pain there is frequently an equally rapid fall in temperature. Thus, of seven hundred and twenty-eight patients treated with salicylates, five hundred and eighty-two were free from pain within seven days. In another series of cases, numbering five hundred and fifteen, it was found that three hundred obtained complete relief from pain in three days. Forty per cent. of these, however, relapsed, the word "relapse" not being used unless there had been decided return of joint pain, accompanied by a temperature above 100°, the condition lasting longer than twenty-four hours. This relapse often proved to be more intense in the character of its symptoms than the initial seizure; and pain and stiffness of joints after the fever had subsided seemed to be more general among patients treated specifically than among those treated on general principles.

Taking as a basis of comparison the estimate that from fifty to sixty per cent. of all patients with acute rheumatism are likely to have cardiac complications, Dr. Hood finds that the proportion of patients treated with the salicylates who suffer from heart troubles is slightly over sixty per cent. He therefore concludes, from this analysis, that the salicylates have no effect whatever in reducing, preventing, or limiting the intensity of cardiac inflammation occurring during the course of acute rheumatism. This conclusion seems entirely just, though some will doubtless think that fifty or sixty per cent. is an over-estimate of the number of persons suffering with rheumatism and treated without the salicylates who suffer from heart complications; and it might even be believed from Dr. Hood's observations that the effect upon the heart of the use of the salicylates is positively harmful, and not almost negative, as the author states it to be.

Dr. Hood calls attention to the dangerous symptoms which have been found to follow the use of the salicylates, especially furious delirium, ushered in by hyperpyrexia. Bearing in mind the fact that the salicylate of soda is capable of producing delirium and hallucinations in persons unaffected with rheumatism, and that rheumatic patients treated with it are peculiarly prone to delirium, the caution which Dr. Hood urges

should be used in administering this drug deserves to be carefully heeded.

In conclusion, he states that he does not consider the administration of the salicylates to be advisable in the rheumatism of children, but regards it as more especially indicated in the acute sthenic rheumatism of early adult life. In other and older patients they are best given only as an anodyne, and in combination with a more general and tonic treatment. In the acute rheumatic attacks of late adult life, many of which are very like those of gout, he is disposed to give the salicylates as an anodyne. The remedy, he says, seems to be contra-indicated in cases in which relapse follows relapse. In attacks which have been complicated with one of the severer forms of cardiac or pulmonary inflammation, he thinks the evidence indicates that the use of the salicylates should be discontinued, if they have already been employed.

THE DIAGNOSIS OF PERFORATING WOUND OF THE INTESTINE.

At the recent meeting of the American Medical Association, Dr. N. Senn, of Milwaukee, made a very remarkable demonstration, before the Section on Surgery, of a method designed by him for determining the fact and location of perforation of the intestine in cases of penetrating wounds of the abdomen. This method consists in injecting hydrogen gas into the rectum and applying the flame of a match to the point at which the abdominal wall has been perforated; and its usefulness for diagnostic purposes depends upon the fact that a flame of burning hydrogen will appear at the wound in the abdomen in case the intestine has been perforated. In demonstrating this interesting and valuable method, Dr. Senn anæsthetized and shot before the Section several dogs, and then injected the hydrogen, applied a flame to the wound in the abdomen, showed the ignition of the gas, rapidly opened the abdomen, and found the intestine perforated. This was all done with astonishing accuracy and rapidity, and won the hearty applause of all present.

So much would be enough to entitle Dr. Senn to hearty admiration; but his method is capable of accomplishing more. Not only does it furnish a valuable aid to determining whether or not a gun-shot or stab wound has perforated the bowel, and whether or not laparotomy is absolutely indispensable; but it also furnishes a means of finding with comparative ease the number and location of any perforations which may have taken place. Dr. Senn's demonstration showed that, after the presence of a perforation was ascertained, and the abdomen had been opened, the gas distended the bowel to the point of the perforation, and made this easy to find. If there were several perforations, after the lowest one was closed the gas distended the bowel up to the next lowest, and when this was closed, up to the next, and so on until all were closed, when the gas could be detected coming from the mouth of the animal experimented upon.

The whole experiment was conducted with a dexterity and ease which filled the spectators with admiration, and left them impressed with the sureness and simplicity of Dr. Senn's method. In our opinion, the demonstration constituted one of the most valuable contributions to the surgery of penetrating wounds of the abdomen which has ever been made public, and we congratulate Dr. Senn most heartily upon the ingenuity shown in devising the method, and upon the skill with which he presented it to his fellow-members of the Association. It is now the common property of the medical world, and we have no doubt that it will prove to be of great aid to surgeons and a great boon to mankind.

OPERATION FOR ABSCESS OF THE BRAIN.

The illness and death of Mr. Conkling, of New York, has attracted attention to the subject of operations for the relief of abscess of the brain, of which we spoke editorially in the Reporter, April 7, 1888. So far as our information goes, no operation such as we cited at that time as having been done by Mr. Victor Horsley, was done in the case of Mr. Conkling, although there was some reason

to believe that an abscess of the brain had followed a suppurative inflammation of the middle ear. The mastoid process was opened, the operation being followed by temporary improvement in the condition of the patient; but this lasted only a short time, and on April 18, Mr. Conkling died.

This painful occurrence calls attention anew to the importance of appreciating the serious nature of diseases of the ear, and of knowing what operative interference may be undertaken when such diseases appear to have extended to the substance of the brain. There appears to be comparatively little danger to life in opening the skull and exploring the brain for a suspected collection of pus, when this is done according to methods now thoroughly understood by well-informed surgeons; and the development of symptoms pointing strongly to the presence of such a collection after inflammation of the middle ear is sufficient justification for the operation referred to. There are no doubt cases constantly occurring in private practice, in which death might be averted if a surgeon with sufficient courage and skill were summoned to advise, and, if necessary, to act in the case. What has been done in Europe can be done here; and there is no more reason why a man should die here than there, with an undetected and untreated abscess of the brain. On February 23, 1888, Dr. John Ashhurst, at the Pennsylvania Hospital, trephined a woman for abscess of the brain following long-standing ear disease. A small quantity of pus and broken-down brain matter was evacuated, and the patient's symptoms were slightly improved, but she died on the third day. An abscess was found at the autopsy.

Trephining for cerebral abscess has also been practised by several other American surgeons, including Doctors Detmold, Noyes, Nancrede, Pancoast, N. R. Smith and Weed.

MURDOCK'S LIQUID FOOD AND DR. CUSHING.

In the REPORTER, May 5, 1888, we published a short editorial note referring to Murdock's Liquid Food, founded upon certain charges made in regard to it by the *Boston Journal of Health*, and others contained in a letter signed "W" in the *Journal of the American Medical Association*, April 21, 1888. The opinions which we repeated were unfavorable to the food, and contained an intimation which was far from complimentary to Dr. E. W. Cushing, editor of the *Annals of Gynecology*. Since the publication of our editorial we have received information which leads us to believe that injustice has been done both to Mr. Murdock and to Dr. Cushing, and that we owe it to both to acknowledge the fact. So far as the food is concerned, it appears to be an article which has proved of great value in the hands of physicians, and deserves to be judged on its merits. We have received the testimony of a number of medical men to its usefulness, and have been confronted with persons who have received much benefit from using it. So much we deem it right to say—contrary to our custom—in these columns, because we think we have before done Mr. Murdock an injustice.

As to Dr. Cushing, we regret that we have given a sort of sanction to an attack upon him, which we have reason to believe was prompted by unworthy motives, and for which he has been unable to obtain, in the pages of the *Journal of the American Medical Association*, the redress to which he thinks he is entitled.

In another part of this issue of the REPORTER we publish, at his request, a number of letters bearing upon his relations to the Hospital supported by Mr. Murdock. These letters seem to entirely justify his claim that his connection with it was formed with a due regard for the professional opinion of his brethren in Massachusetts, and after due consultation with those who might be supposed to know and voice their ethical sentiments. His position is one which has subjected him to criticism which he could hardly expect to escape; but he has a right to complain that some of it has been unfair and unjust, and we cannot refuse his request for a presentation in the REPORTER of the documents which some of his accusers have gone so far as to insinuate that he could not produce.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

ON A NEW TREATMENT OF CHRONIC METRITIS, AND ESPECIALLY ENDOMETRITIS, WITH INTRA-UTERINE CHEMICAL-GALVANO-CAUTERIZATIONS. By Georges Apostoli, Free Professor of Electro-Therapeutics at the Practical School, etc. Translated by A. Lapthorn Smith, Z.A., M.D., M.R.C.S., Eng., etc. 8vo, pp. 119. Illustrated. Detroit: Geo. S. Davis, 1888.

The impression left on our mind after carefully reading this book is that Dr. Apostoli is an enthusiast. This fact, however, does not make his book any less interesting. The author briefly discusses the nature and etiology of metritis and endometritis. He considers that these diseases are usually caused by an arrest in the process of involution, after labor or abortion. He would limit the use of Faradism to the treatment of subinvolution and the early stage of chronic metritis. This disease in its later stages is treated by intra-uterine galvano-chemical cauterization. The necessary apparatus is described at length, special stress being laid upon the importance of using the galvanometer, the author's clay electrode for the abdomen, and a battery which will furnish a current of 200 to 250 milliampères. The method of operating and the nature of the effect produced are also fully described, and many practical hints are given. The attempt is made to answer objections to the method in advance. The work concludes with an appendix containing, among other things, abstracts of the author's various monographs upon electro-therapeutics. As would be expected of a supporter of an exclusive method of treatment, Apostoli underrates the value of other therapeutic resources. Nor has he presented a method of treatment without disadvantages. Not to mention others, atresia of the uterine canal is a not uncommon result of the cauterizations. Still the book will be useful to those interested in the application of electricity to gynecology.

A COMPEND OF HUMAN PHYSIOLOGY, ESPECIALLY ADAPTED FOR THE USE OF MEDICAL STUDENTS. By Albert P. Brubaker, A.M., M.D., Demonstrator of Physiology in the Jefferson Medical College, etc. Fourth edition, revised and enlarged. 12 mo. pp. 174. Illustrated. Philadelphia: P. Blakiston, Son & Co., 1888. Price, $1.00.

This is an admirable compend of physiology, including enough of anatomy to fit it especially for the use of students of medicine. It has been prepared by one who is fully fitted by his work as Demonstrator in the Jefferson Medical College and as Professor of Physiology in the Pennsylvania College of Dental Surgery, and by his experience as a quiz-master, to compile such a book, and it has proved its utility by the acceptance it has already found. Its style is clear and distinct, its teachings are sound, and it is well suited to the purpose for which it is intended.

THE ESSENTIALS OF MEDICAL CHEMISTRY AND URINALYSIS. By Sam E. Woody, A.M., M.D., Professor of Chemistry and Public Hygiene, etc., at the Kentucky School of Medicine. Second edition, revised and enlarged. Illustrated. 8vo, pp. 140. Louisville: John P. Morton & Co., 1888. Price, $1.25.

This little book is intended for the use of medical students, and presents only the facts of chemistry which are most important to this class of readers. The manner of presenting these facts is plain and terse, and the selection of them is excellent. In the department of analysis of the urine there is a very good account of the methods of conducting a chemical examination, and a number of good cuts illustrate the matters to be recognized in a microscopical examination.

THE SALIVA AS A TEST FOR FUNCTIONAL DISORDERS OF THE LIVER. By Samuel Fenwick, M.D., F.R.C.S., Physician to the London Hospital. 8vo, pp. 78. London: J. and A. Churchill, 1887. Price, 75 cents.

This admirable essay contains one of the most suggestive studies in physiology which we have ever examined. The object of it is to show that the amount of sulpho-cyanide of potassium found in the saliva is an indication of the functional activity of the liver. The author's opinions, which are stated with great clearness and with commendable scientific reserve, rest upon a large number of careful observations, and exhibit an admirable illustration of the inductive method of reasoning. The way in which his investigations were conducted is so simple that any medical man who is not color-blind can easily imitate them, and it ought not to be difficult to confirm or correct his conclusions. It is to be hoped that this will be done soon, and we hope that a number of our readers will get his interesting little book and repeat his experiments, so that we may learn in this country if his suggestions contain—as they appear to—a very valuable theory in regard to nutrition in general, and functions of the liver in particular.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—In accordance with a resolution adopted by the Faculty of Medicine of the University of Pennsylvania, the first number of a sixty-four page medical monthly will be issued October 1, 1888, under the title, *The University Medical Magazine.* It will be edited by an advisory committee of the Faculty, but more directly by Dr. George E. de Schweinitz and Dr. Hobart A. Hare. It will contain original articles and clinical lectures by the members of the Faculty and other teachers in the University. It will also contain reports of the practical work done in the laboratories of the Medical School, the Dental, Veterinary and Biological Departments. The profession will thus receive the current teachings of the University, together will publish items of interest to the undergraduates and reports of the work done in the Medical Societies connected with the Medical School. The price of the magazine is to be two dollars a year. The publisher is A. L. Hummel, Philadelphia.

—The attractive side of "Hospital Life" will be presented in *Scribner's* for June by one who looks at it from a patient's point of view. It contains bits of humerous and pathetic character-sketching. J. Alden Weir, W. L. Taylor, and other skillful artists have made drawings in the New York and Brooklyn Hospitals to illustrate it.

Correspondence.

Dr. Cushing and the Murdock Food Hospital.

The following correspondence is published at the request of Dr. E. W. Cushing, of Boston, who states that he has been refused a similar request by the Editor of the *Journal of the American Medical Association*, after the publication of a letter which reflected very severely upon his professional conduct in connection with Murdock Liquid Food Hospital.

Extract from letter of W. *in the Journal of American Medical Association, April 21, 1888:* [1]

* * * * In the meantime Dr. Marcy, who had severed his connection some time previously to any thought of the discussion, published in the *Boston Medical and Surgical Journal*, a card stating his previous withdrawal from the Murdock Hospital, and giving as his reasons for so doing that the hospital was not acting up to its agreement, in regard to running and management of the hospital. Immediately, Mr. Murdock replies in the following number of the same journal, contradicting flatly some of Dr. Marcy's statements, and referring to letters of the Council of Ethics of Massachusetts Medical Society, in commendation of the enterprise, which in the next issue of the *Journal*, was flatly contradicted by the Council, thus leaving the way open for Dr. Cushing to show the letter which they claim he has not. * * * * W.

1. DR. CUSHING TO DR. TOWNSEND.

Boston, Oct. 8, 1886.

Geo. J. Townsend, M.D.,
Chairman of Committee on Ethics,
Mass. Medical Society.

Dear Sir:—After my interview with you, on the subject of accepting a position as Visiting Surgeon of the hospital now nearly completed by the Murdock Liquid Food Co., on Huntington Ave., Boston, I visited at your suggestion Dr. Johnson, at Salem, and Dr. Francis, at Worcester, your colleagues on the Committee of Ethics, and laid the matter fully before them, explaining as I did to you, that I was not merely inquiring whether there is anything about accepting the position, which would be a subject for reproof or discipline, but that I was solicitous to know whether considered broadly there is anything in such a connection contrary to the interests and honor of the profession.

As I understood from these gentlemen their views coincided with those you expressed to me, viz.: That there was nothing in holding such a position unethical or subject to discipline according to the laws of the Society. That so far as appears at present, and if the hospital is managed as it should be, and as Mr. Murdock promises that it shall be, there is nothing undignified nor blameworthy in acting as a surgeon to it. That as the case is wholly without precedent and may become a subject of imitation, it is peculiarly incumbent on the medical staff to avoid any appearance of unprofessional conduct. That I must expect considerable criticism and animadversion, which must be met by frankness, and will disappear if my future course corresponds with my present intentions as expressed to the members of the committee.

Remembering that at our interview you said that, if any further doubts or objections should appear to you, you would write to me and hearing nothing from you I have concluded that there is nothing to prevent me from accepting Mr. Murdock's request, and take this opportunity of accepting the position he offers.

I shall have no interest whatever in the company. I shall have full charge of the medical and surgical treatment of patients. I am under no obligation to use the "food" for the patients; but I can have it fresh, and gratis for them, and propose to give it a fair trial. I am at liberty to give instruction to post-graduates, I have no connection with the homœopaths, who have rooms under the same roof but with no communication, and with entrance on another street. I have nothing to do with the advertisements and financial management of the hospital. Nevertheless, Mr. Murdock has seen his way to modify his advertisements in consideration of the susceptibilities of the profession, as you will see by referring to the later numbers of the *Boston Med. and Sur. Journal.* In short, my duties are to be similar to those of the professional editor of a medical journal owned by a commercial firm. My name is not to be used in advertising, in any lay journal especially not.

Under these circumstances Dr. Henry O. Marcy has consented to act as consulting surgeon, and I expect that other well-known members of the profession will similarly accept. We propose to give a course to physicians beginning next January.

This then, Mr. Chairman, is the programme as proposed, and I bespeak for it your favorable opinion. I fully realize the importance of discretion in the management of this mat-

[1] W. is said to be Dr. Geo. W. Nash, formerly assistant to Dr. W. O. Marcy.

ter, which may have imitators in these days of innovation. I also, however, fully believe that such an agency for good or evil should be properly guided and made a convenience to the profession as well as to the public, instead of letting it fall into the hands of irregulars or unscrupulous medical men.

If at any time you observe anything connected with my functions at the hospital which seems to you contrary to the dignity of the profession, I pray you to advise me of it fraternally and I will try to remedy it. In conclusion, let me add that Mr. Murdock feels, and states with emphasis, that his object in supporting this Hospital is not solely a commercial one, but that he has fully his share of philanthropic motives and a desire to be useful, such as influence medical men in giving their time and work to hospital service. Yours respectfully,

ERNEST W. CUSHING.

2. DR. TOWNSEND TO DR. CUSHING.

South Natick, Oct. 16, 1886.

Ernest W. Cushing, M. D.,

Dear Doctor:—I duly received yours of the 8, and press of business has delayed my answer, which I have not regretted, as I have no objections to urge against your plans. Your propositions all represent correctly the opinions of the Committee on E and D (Ethics and Discipline) as far as I have had opportunity to learn them. I had a conversation with Dr. Johnson at the meeting of the Council. Dr. Francis was not present, you have stated his views correctly. As to the policy of assuming your position, it is not for us as a committee to decide, and, as you suggest, the idea is so new that for one I do not feel competent to advise. I have read Murdock's last advertisement and there is nothing in it that is in the least objectionable. Plenty of the members of our Society use the food, and it is advertised as a food, and not as a medicine.

Farther, I see no reason why we should deny to him all philanthropy, even if at the same time he advances his own interests.

Trusting that your experiment will prove successful, profitable and agreeable and with kind remembrances to Dr. Marcy, I am yours very sincerely, GEO. J. TOWNSEND.

3. DR. CUSHING TO DR. TOWNSEND.

Boston, Oct. 20, '86.

Geo. J. Townsend, M. D.,

Chairman of the Committee of Ethics and Discipline, Mass. Med. Society.

Dear Sir:—Your favor of the 16th inst. was duly received, and contents noted with much pleasure. I thank you very much for the good will and moral support expressed in your letter, and assure you that I shall do everything in my power to continue to merit your confidence.

Dr. Marcy thanks you for your remembrance, and desires me to express his kind regards to you. I believe that Dr. Henry J. Bowditch has consented to act as consulting physician to the hospital.

Yours sincerely,

E. W. CUSHING.

(In the correspondence furnished us, there follows here a letter—No. 4—from Dr. Marcy, dated Feb. 15, 1888, and one from Mr. Murdock—No. 5—dated Feb. 24, 1888, which have already been published in the *Boston Med. and Surg. Journal.* We do not reprint them, for want of space.)

6. DR. GOSS TO THE BOSTON MEDICAL AND SURGICAL JOURNAL.

BOSTON, March 12, 1888.

Mr. Editor:—Owing to correspondence published in the *Journal* of the 1st inst., the Committee on Ethics and Discipline desire to make the following statement:

Shortly before the Councillor's meeting in October, 1886, Dr. E. W. Cushing called upon three members of the committee separately, and asked for a formal opinion as to the propriety of his accepting the position of surgeon to the Murdock Liquid Food Hospital. Each member declined to express an official opinion, but each stated his views. October 8, 1886, Dr. Cushing addressed a letter to the Chairman of the Committee stating his relations to the Hospital, but he did not request action by the Committee.

The Committee had never been asked to consider the subject, and they desire to say that if asked, they could not have done so without exceeding to powers delegated to them. Very respectfully,

FRANCIS W. GOSS, M.D.,
Secretary.

—The *Chemist and Druggist*, May 12, 1888, states that the German authorities officially notified the officers of the Strasburg Medical Society, on April 30, that the society had been dissolved, and forbidden to meet again under penalty of fine and imprisonment. The reasons for this suppression are unknown, as the men composing the society were of high rank in the profession, and politics were rigidly excluded from it. The German government never showed by word or sign that the society had incurred its displeasure.

Notes and Comments.

A Home for Physicians.

At the recent meeting of the Alabama State Medical Association, April 10, 1888, Dr. Edward H. Sholl, in his Presidential address, proposed the founding of a Home or Retreat for aged physicians, or the widows or orphans of physicians. In explaining his idea, he said: "I mean distinctly some ample provision by which some Home or Retreat shall be erected, which shall be the property of and the care of the Medical Association of the State of Alabama, where in the years to come, as annual contributions, endowments and legacies come in, shall be gathered, for instruction and comfort, not only the orphans of our brethren with all the appliances for preparing them to deal with the practical issues of life, but also the widowed, who by the payment of a moderate sum, if able, or by gracious beneficence, if not, shall find such a welcome shelter for a time, or life, if needs be, as shall make the burdens and sorrows of life more readily borne, and brighten the infirmities of advancing years that would otherwise be lone and cheerless.

"Here also the superannuated of our profession, either infirm from the weight of years or bodily affliction might come, those without kith and kin, but with a moderate income to provide for themselves the luxuries of a comfortably appointed home with congenial surroundings, and give themselves over to the rest they have well earned.

"Here, too, might come those of our number, worthy, upright men, sick, homeless, penniless, almost baffled by adverse fortune, to seek rest and renewing of health, made freely welcome by the rich bounty of others to those comforts long denied them, to go out again refreshed and reinvigorated to the duties of life, or to find tender hands to nurse, tender sympathy to watch the decline of life, and at last to close the sightless eyes and fold the cold still hands upon the breast of another way-worn pilgrim, who has reached his journey's end."

"Analgesine."

Antipyrine, says the *Chemist and Druggist*, May 5, 1888, is hereafter to be known and dispensed by the Central Pharmacy and all the Paris hospitals under the name "analgesine." At a recent meeting of the Academy of Medicine of Paris, Prof. Bourgoin announced this fact, and expressed the hope that all physicians in civil practice would follow the example to thwart an oppressive monopoly. His remarks were greeted with great applause. This action is in accordance with a decision of the director of the Paris *Assistance Publique*, that henceforth prescriptions calling for antipyrine shall be filled by the Hospitals' Central Pharmacy with analgesine or dimethyloxyquinizine.

A Dangerous Prescription.

The *American Druggist*, April, 1888, says: The following prescription was presented to a friend of one of our correspondents:

℞ Antipyrini.....gr. 15
Spir. æther. nit.....fl. ʒ 2
Tr. aconit. rad.....gtt. 8
Syr. lactucarii.....q. s. ad....fl. ʒ 2
M. et signa: Dose: One teaspoonful.

This prescription was prepared and produced a green solution, and one teaspoonful was given to a patient, a little boy of five years of age, and who was not by any means sick or confined to his bed, but seemed to be ailing with a little fever. After taking the first teaspoonful, the child was thrown into convulsions, and died in about two hours.

In explanation of the reaction taking place between antipyrin and spirit of nitrous ether, we would state that the incompatibility of the former with nitrous acid or nitrites, in presence of acids, has long been known. In fact, the reaction has been used both as a test for nitrous acid as well as for antipyrin.

In dilute solutions containing nitrous acid, antipyrin causes a bluish-green coloration. In concentrated solutions it produces a precipitate of bluish-green crystals, consisting of *iso-nitroso-antipyrin.*

Now, it is well known that nitrites in general are active poisons. Even small doses of an alkali nitrate, for instance nitrite of potassium or sodium, say 5 to 8 grains, produce a throbbing and a sensation of bursting in the head, with vertigo, eructations, nausea and vomiting, cyanosis, and often convulsions. Free nitrous acid is still more energetic, even in very small quantities. The new substance produced by the reaction between antipyrin and spirit of nitrous ether appears to belong to that class of bodies in which the effect of the presence of an active radical is greatly intensified. Yet neutral nitrites do not produce the above-mentioned reaction with antipyrin. It is necessary that the nitrous acid be in a free state. If this is the case, the bluish-green or pale green color will appear on the addition of a solution of antipyrin. When this color is once developed, it is not destroyed or removed by the addition of an alkali. But if the free nitrous acid is first neuralized with an alkali, the addition of antipyrin will fail to produce any color reaction.

Experience Among Russians in the Treatment of Small-pox.

Reimer (*Archiv für Kinderheilkunde*, Bd. ix. H. 1.) says his experience includes the treatment of thirteen hundred cases. When the pustules were covered with Weidenbaum's ointment (consisting of mercurial ointment, soap, and glycerine) they developed rapidly, but very painful irritation resulted, and the febrile process was not shortened. With a solution of India-rubber the children complained of great burning, and in four cases septicæmia resulted. Nitrate of silver applications seemed only to make the scars deeper. Hebra's iodine bandage caused great pain. The pustules became confluent in great scabs, which soon fell off, but the application had slight influence in respect to scarring. In forty-six cases applications of sublimate were made with great care. A mask was moistened with a solution of 1 to 500, and applied to the face four times daily for periods of ten minutes each. The development of the pustules was hastened thereby, but there was no perceptible influence upon the scarring process.

Schwimmer's paste of carbolized oil was found difficult of application upon a mask. A paste was then made from carbolic acid, talc, chalk, and starch, and applied four times daily in seventy-seven cases. The results were unfavorable. In thirteen cases there were symptoms of carbolic acid poisoning; in twenty-six there was nephritis, and in seven hæmaturia. Burkhardt and Zulzer's treatment with xylol was tried in fifty-two cases without any effect as to the scars. Other methods were equally unsuccessful. Salicylic acid was then tried in fifteen cases, as recommended by Schwimmer and Claridge, five grains being given every two hours, and in all the cases the duration of the disease was shortened. Microscopical examination of the blood in the early stages of the disease showed that after six days' treatment with salicylic acid the rod-like bacteria which had previously been found had disappeared.—*Archives of Pediatrics*, April, 1888.

Plea for Small, Frequently Repeated Doses.

Dr. Charles C. Partridge, of Kansas City, says when he first started out in medicine he hooted at the idea and doubted that a minim dose of ergot repeated every hour would have a contractile effect upon the womb and that it would control a hemorrhage from that organ, until he was led to try it. A minim dose of tincture of aconite repeated every hour or two will frequently cut short an attack of capillary bronchitis or pneumonia in children. No less an authority than Sidney Ringer claims this, and yet we know that often it is prescribed in larger doses, although it is a powerful cardiac depressant. Who, he says, has not witnessed the wonderful effects of this drug in minim doses in cutting short an attack of quinsy? A minim dose will act just as well in the latter case, repeated every hour, as three or five minims will. If anyone doubts it, he advises him to try it and be convinced.

Ten years ago, he says, we thought that it was absolutely necessary to give from five to ten grains of calomel in order to get good cathartic effects from this drug, and yet we can get just as satisfactory results to-day from the 1-20 of a grain repeated every hour as we can from giving five or ten grains.

Again, take the new and valuable drug, antipyrin, ordinarily prescribed in fifteen grain doses every two to three hours until the temperature falls. He says he recently, in a case of acute articular rheumatism, gave eight grains three times a day, and obtained toxic effects, although the patient's suffering was allayed, but found it necessary from the photophobia and other symptoms of disordered vision to reduce this dose to four grains at night, when these symptoms disappeared. In fever, no matter of what nature, one grain every three hours will produce very soon a slowed pulse and copious diaphoresis. He says his experience justifies the statements made.—*Kansas City Medical Index*, March, 1888.

Resorcin in Some Gastric and Cutaneous Disorders.

Dr. Edward Mackey, in a communication on this subject in the *Lancet*, March 24, 1888, reports seventeen cases of gastric ulcer or catarrh, presenting varying degrees of chronicity and severity, of which he has retained sufficient notes to justify a conclusion. They were all women except one. Most of them had taken, at various times, bismuth, prussic acid, alkalies or acids, rhubarb, etc.; and one of them—a woman at the climacteric—failed to attribute decided benefit to the resorcin, and to ask for it again. He has met with no drawbacks from its use, such as causing pain, vomiting or constipation; in a few cases, however, when giddiness which occurred might have been due to it, he has lessened the dose to three grains; the usual one was from four to five grains in one tablespoonful of chloroform water, to which plain water would be added.

Small-pox in the United States.

Surgeon-General John B. Hamilton, of the U. S. Marine Hospital Service, reports, sixty cases and four deaths from small-pox in Philadelphia up to April 18; of seventy-nine cases in New York up to April 19; of forty-three cases and seven deaths in Brooklyn up to April 20.

Treatment of Laryngitis.

The London correspondent of the *Canada Lancet*, April, 1888, says that Dr. Wolfenden, of the London Throat Hospital, in cases of sub-acute laryngitis prescribes the following:

℞ Tinct. benzoini co.,.....f℥iv
Sig.—A teaspoonful in a pint of hot water for each inhalation, night and morning.

The patient is cautioned not to go out of doors for at least half an hour after using the inhalation. Trochees of krameria are also ordered, each lozenge containing one or two grains of the extract of rhatany.

In some cases the following vapor is preferred:

℞ Olei eucalypti.....f℥ij
Magnes. carb. levis, grs. lx;
Aquæ ad.....f℥iij
To be used in the same manner as the above.

In chronic laryngitis, in addition to any constitutional treatment which may be required, he usually prescribes the following vapor:

℞ Olei pini sylvestris.....f℥ij
Magnes. carb. levis, grs. lx;
Aquæ ad.....f℥iij
Sig.—A teaspoonful in a pint of hot water for each inhalation, night and morning.

He also gives trochees of krameria.

In tuberculous laryngitis he prescribes a vapor of benzoin and chloroform, as follows:

℞ Tinct. benzoin co.....f℥j
Chloroformi.....♏iv
Put in a pint of hot water for each inhalation.

As a local application he uses solutions of lactic acid, varying in strength from twenty per cent. to sixty per cent., applied by means of a brush, twice a week. In granular pharyngitis he finds the galvano-cautery the most satisfactory treatment.

Pasta Mack.

Pasta Mack is a new toilet preparation which dissolves in water with evolution of carbonic acid gas, and is said to produce an agreeable and refreshing effect upon the skin. According to Eckstein in *Berliner Pharm. Zeitung*, it is composed of a mixture of 27 parts rice starch and .73 parts effervescing powder (bicarbonate of sodium 10, tartaric acid 9), suitably perfumed and formed into small tablets. The perfume imparted to the water is strong and agreeable and remains upon the skin long after washing.—*Am. Journal Pharmacy*, May, 1888.

Abscess of the Liver; Operation; Recovery.

Dr. G. A. White reports the following case: Chas. C——, 38 years old, a miner, was admitted to the Sacramento County Hospital, Nov. 19, 1887, suffering with abscess of the liver. His primary illness dated from December, 1886, eleven months previously, when, from the history given by himself, he must have had an attack of malarial hepatitis. The patient presented a bronzed appearance, was greatly emaciated, had high fever, and was profoundly exhausted on account of his railroad trip from a neighboring county. Liberal doses of quinine and whiskey with morphine hypodermically were given for two days, when sufficient reaction had taken place to warrant operative interference. The borders of the sac were tolerably well defined, the abdomen was prominent, about as large as a woman's abdomen at the eighth month of pregnancy. The upper border of the sac crowded up the diaphragm, so that respiration was attended with difficulty. Fluctuation could be detected in the lower intercostal spaces, as well as over the right half of the abdomen. Selecting a point at the ninth intercostal space, the abscess was opened by an incision about one and a half inches in length, and two gallons of pus discharged. The cavity was freely irrigated with warm carbolized water, a large drainage-tube was inserted, and an oakum dressing completed the operation. The after treatment consisted of irrigation of the sac twice daily for two weeks, and afterwards but once a day, with a solution of boracic acid (one drachm to one pint of warm water). The large drainage-tube was replaced with a double tube of smaller size. Later on, a single tube was used as long as pus discharged. When the discharge became serous the wound was kept open with a tent of saddler's silk, until finally the discharge ceased altogether. Opium pills were given when necessary, for a few days after the operation. The patient was put upon a milk diet with milk punch, and gradually fed up to a full diet; little medicine, other than tonic doses of quinine and iron, was needed in the treatment. The patient made a complete recovery, and was discharged cured February 3, 1888.—*Sacramento Medical Times*, April, 1888.

Electrolysis in Stricture of the Rectum.

At the meeting of the Baltimore Academy of Medicine, March 6, 1888, Dr. S. T. Earle reported the progress of a case of stricture of the rectum from syphilis, which he was treating by electrolysis. This treatment was necessarily slow. The patient had had the stricture six or seven years, and had been operated on two years ago, when linear proctotomy was performed, which was not followed by dilatation, and so it grew up tighter than before. It was the worst case Dr. Earle had ever seen. On introducing the little finger into the rectum he could not even feel the indentation at the point of the opening. He succeeded in introducing a small silver probe. She was able to have fluid stools, but only with straining. His first intention was to do linear proctotomy, but concluded to use electrolysis as a matter of trial. He used a Barrett battery, introducing the electrode with steady pressure, without force, for ten to fifteen minutes, and using ten cells. This was done at first once a week, and the opening grew larger as the size of the electrode was increased. He had so far eight sittings, and on the day of making his report he had introduced a bougie, two inches in circumference at the large end, almost all the way in. There was less straining and little pain now, and the stools were partly solid. There was a neoplasm in Douglas's *cul-de-sac*, and this was being absorbed by the current. The positive pole was placed over the abdomen, and not on the buttocks. He was very much pleased with the progress thus far, and will report future progress. In answer to Drs. Uhler, Ashby and others, Dr. Earle stated that a sitting generally lasted from fifteen minutes to half an hour. The negative pole was in the stricture, and the irritation and pain from it soon subsided. He had used as high as fifteen cells with the largest electrodes.—*Maryland Medical Journal*, March 24, 1888.

Results of Mechanical Treatment of Hernia.

In the *N. Y. Med. Journal*, March 3, 1888, Dr. W. B. DeGarmo gives an analysis of one thousand cases of hernia occurring in private practice, and the results of mechanical treatment. In concluding his article, he says that out of the entire number of hernias, 1,203, a little over one-quarter (or 336) have been cured, and, as shown by the table, 463 were improved, 312 were retained, 5 were abandoned as unmanageable, and in 87 the result was unknown.

The study of the foregoing cases, he says, leads to the following conclusions:

1. That by early mechanical treatment a large percentage of hernias occurring under middle age can be cured.

2. That, while there is no intent to underrate the value of surgical measures in suitable cases, it is believed that the greatest relief to the greatest number can be afforded by the more careful and scientific mechanical treatment of hernia.

3. This end can be attained only by the personal attention of the practitioner, instead of allowing such cases to go into the hands of unprofessional and incompetent persons.

Venesection in Puerperal Eclampsia and Pneumonia.

Dr. Hiram Corson, in a letter to the *Medical Standard*, April, 1888, says: I have greatly deplored the fatality which has resulted from the treatment of this affection by or with the various depressants in lieu of venesection which in these cases is not a depressant but a reliever of depression. It brings just such relief to the patients as the removal or elevation of a portion of depressed bone by a surgeon brings to the patient who lies unconscious before him. In all the cases which I have seen in over fifty-nine years' practice, I bled freely—sometimes ferociously, pardon the word—and all recovered. Still more frequently have I averted the convulsion by a timely bleeding when the symptoms heralded the coming of convulsions.

What crowds of women have been lost by the physician who waited for the slow action of potassium bromide, chloroform, veratrum viride, aconite, ether, etc., etc. It is horrible to have men who have seen a patient bled, teaching that "no one has any blood to spare," "that it is a murderous practice." Pretty teachers they are! They do not even know the effects of the agents which they praise. Many of our medical teachers know nothing of general practice. They are filled with hospital notions; one of which is, that nearly all diseases are the result of syphilis, and on that opinion they base their treatment.

Important as is this subject, there is another which is of equal importance; the treatment of pneumonia. Under the old "murderous" treatment it was one of the most manageable of diseases, yet it now sweeps off people by scores. I would be ashamed to lose a patient, old or young, ill with this disease. Yet teachers, scared by homœopathic assailants of venesection, blatantly denounce a practice they have never witnessed, and as blatantly praise poisons which are useless in small doses and dangerous in those which give rise to their specific symptoms.

Experiments in Implanting Teeth.

Dr. Younger, of San Francisco, has demonstrated that it is practicable to replace lost teeth, even after the socket has been filled up with bony substance. He simply drills into the jaw, gouges out a new socket, and then, taking a foreign tooth that has long been extracted, cleans it thoroughly, soaks it in bichloride of mercury and inserts it in the socket thus artifically formed. Describing this process, *Science*, March 23, states that Dr. W. M. Gray, the microscopist of the United States' Surgeon General's office, has examined a tooth which had been implanted by Dr. Younger's method and then extracted. Dr. Gray's microscopical examination shows beyond question that the tooth so implanted is actually revived, that circulation is established between the socket and the implanted tooth, and that the socket takes an active part in anchoring the tooth. Dr. G. M. Curtis, of Syracuse, N. Y., has successfully repeated Dr. Younger's experiment, and found that a tooth which he had implanted was so firmly anchored that it broke when he was extracting it. As good teeth are indispensible to proper mastication, and hence to nutrition of the body, the discovery of means for replacing them when lost is a very valuable contribution to dentistry.

Molasses in Conjunctival Affections.

Dr. Henry F. Wolfner, says: "About one year and a half ago, I was told by several practitioners who attended the Post-Graduate School, that there had been a traveling eye doctor in their neighborhood, who was very successful in the treatment of chronic conjunctival inflammations; the remedy he used looked like molasses and tasted sweet. Knowing that sugar had been used, at least in the lower animals, in interstitial corneal infiltrations with considerable success, and that it was still sometimes applied to granulating ulcers for its slight caustic effect, I classed molasses with the other irritants, and made up my mind to see if there was any special virtue in this new medicament. It has now been used in almost every case of chronic conjunctival affection that I have seen at the clinic, and for the last year I have also used it in private practice. My observations lead me to believe that it has some special virtue, as cases which had formerly been treated with sulphate of copper, nitrate of silver and jequirity unsuccessfully, almost immediately commenced to get better under its use. Most good has been accomplished in those chronic cases, in which although the granulations have become flat, the pannus the result of the granulations, has not disappeared. According to the amount of stimulation the eye will bear, the instillations are made every day, every other day, or only once or twice a week. The mode of application is very simple; a small quantity of molasses is taken up on a probe and allowed to drop into the everted, lower, retrotarsal fold of the conjunctiva."—*St. Louis Courier of Medicine*, April, 1888.

Cancerous Uterus Completely Removed by Chloride of Zinc.

At the meeting of the Clinical Society of Maryland, March 2, 1888, Dr. B. B. Browne exhibited the specimen from this case and stated that the patient was thirty-five years of age. She had suffered from all of the symptoms of cancer, viz.: Pain, hemorrhage, etc. He attempted to treat the cancerous mass with chloride of zinc. Previous to its use he had curetted the tissue and had used the thermo-cautery. The chloride of zinc was then applied in a saturated solution by means of tampons. These were protected by absorpent cotton, and below this another tampon was placed, saturated with bicarbonate of soda and vaseline. On the seventh day the tampon was removed, and on the tenth day the uterus sloughed and came away. There was no rise of temperature at any time. The patient suffered considerable pain which was controlled with morphine hypodermically. At this time the patient is going about and there is no evidence of any return of the cancer.

Dr. W. P. Chunn asked Dr. Browne if it had been his intention when he began treatment to remove the uterus in this unique way, and also if he would recommend it in the treatment of a similiar case. Dr. Browne replied that he did not expect to remove the whole uterus in this way when he began the treatment. Its success in this case would seem to recommend it favorably for further trial.—*Maryland Medical Journal*, April 7, 1888.

Oil of Peppermint as an Antiseptic and Remedy in Phthisis.

W. Leonard Braddon reports in the *Lancet*, March 24, 1888, very encouraging results from the employment of oil of peppermint as an antiseptic, and as a remedy in phthisis and diphtheria. In phthisis he employed the drug by inhalation, while in diphtheria it was freely and copiously applied to the diseased surfaces twice daily.

NEWS.

—Dr. James Orr, a prominent dentist in Pittsburg, committed suicide May 16.

—A new ward for the Massachusetts General Hospital, to be devoted to abdominal surgery, has been begun.

—Professor Wroblewski, of Cracow, has recently died of blood poisoning, which he suffered as the result of an experiment in the lecture-theatre.

—Dr. Engelhardt, of Halle, has been appointed Professor Extraordinary of Gynecology at Jena, in place of Professor Küstner, who has gone to Dorpat.

—St. Agnes' Hospital, in Philadelphia, was dedicated and formally opened May 16. It is under the care of the Sisters of Charity, and will accommodate 300 patients.

—Professor Lichtheim, of Berne, has accepted the position of Director of the Medical Clinic at Königsberg. He succeeds Professor Naunyn, who has gone to Berlin.

—Dr. Howard Pinkney, a graduate of the College of Physicians and Surgeons of New York, class of 1860, died May 14, while in a railway train in England, whither he had gone to improve his health.

—A Vienna correspondent, says the *Chemist and Druggist*, May 5, 1888, reports that chemical analysis of the Carlsbad water known as the "sprudel," has established the fact that it contains gold. Possibly the spring from which the "sprudel" is drawn must in its course have become combined with a subterranean well which has passed through a gold-bearing stratum.

—The *Lancet*, May 5, 1888, states that Dr. John McIntyre has had a Union Club building erected in the grounds of the University of Glasgow. The building contains a library, a hall for debates, a dining-room, convenient committee rooms, and every arrangement for a perfect house of its kind. It cost about twenty-five thousand dollars.

—A committee of the Board of Overseers of Harvard College at a recent meeting, reported in favor of prohibiting all intercollegiate contests, and the placing of the supervision of athletic exercises in the university itself under the control of a committee in which the faculty shall have a stronger influence. A minority report submitted by Dr. Walcott advised that the formal intercollegiate contests be limited to Yale, and should take place only at New Haven, or Cambridge, or some other New England city or town. The Board of Overseers decided substantially in favor of the minority report.

HUMOR.

True to his Motto.—Patient—"Then you think its all up with me, doctor?" Doctor—"I'm afraid so." P.—"Well, we must all die once, and I may as well go now as afterward. You're sure I'm going?" D.—"Yes."

P.—"Then let me have your bill."

D.—"My bill! My dear sir, this is very unusual. You should give your thoughts to more serious matters."

P.—"My motto has always been 'pay as you go,' and now that I am going I want to pay."

So he paid and went.—*Boston Courier.*

A Growing Child.—Conductor—"Madam, did I understand you to say this girl is not yet twelve years old?" Mother—"She will be twelve next spring." "And you want to go all the way to New York in this car?" "Yes." "Then you should not go on this train." "Why not?" "Because this is a slow train, and if that girl keeps on growing as she has been, by the time we get to New York she will be so large that she will not be able to get through the car door. The company can't afford to take the car to pieces on a half-fare ticket."—*Texas Siftings.*

Bright Literary Prospects.—Friend (to young writer)—"What do you hear from the *Every Other Monthly Magazine*, Charley, in regard to your MS.?" Young writer—"It came back to me a day or two ago with 'many thanks of the editors for my kindness in giving them the privilege of seeing it.' Mind you, Gus, not the thanks of a single editor, but the thanks of every one of 'em on the magazine, and there may be a dozen for all I know. I tell you, Gus, that was a great article, and I'm going to send them something else in a few days."—*The Epoch.*

Thrilling Adventures with the Indians.—Omaha Dame—"You have lived in the West many years, you say?" Domestic—"Yes, ma'am, I crossed the plains with a family many years ago, and was captured by Indians. They was a lazy set o' vagabonds, and made me do all the cooking for 'em." "Dear me! How did you escape?" "I didn't escape, ma'am, as long as there was one of the tribe alive, but at last there was none left and I got away." "Were they killed by the soldiers?" "No, ma'am. The agency doctor in whose family I worked afterward said as how he thought they died of dyspepsia."

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

SOMETHING NEW.

ELIXIR OF COCA AND CALISAYA

which represents the virtues of these drugs in a *most active and palatable form.* The process of manufacture is ENTIRELY ORIGINAL—that of direct fermentation from the bark and leaf—and we claim that better results can be obtained from this preparation than from any other combination of *Coca and Calisaya* now made.

Clinical Lecture.

HÆMOPTYSIS: CONSECUTIVE TUBERCULOSIS.

A Clinical Lecture[1] delivered in the Hôpital Pitié,

BY PROFESSOR S. JACCOUD,

MEMBER OF THE FACULTY OF MEDICINE, AND OF THE ACADEMY OF MEDICINE, PARIS, FRANCE.

Gentlemen:—For thirty years I have defended Morton's theory of phthisis by hæmoptysis; I have shown from my own personal observations that the causal influence of hæmoptysis on the development of tuberculosis is explicable by my doctrine of pulmonary *hypotrophy;*[2] and I have reported in my *Clinique de l' hôpital Lariboisière,* as well as in my "Curability and Treatment of Pulmonary Phthisis," numerous cases which prove clearly this relation of cause and effect between hæmoptysis and tuberculosis.

But however convincing they may seem to be, none of these observations equal in precision, in demonstrative value, that which is the subject of my lecture to-day; here the causal influence of hæmoptysis is put beyond the shadow of a doubt, and what is more, the autopsy has confirmed this etiological judgment in a striking manner.

A robust man, 48 years old, a painter, came under my care, in ward Jenner, No. 7, on the fifteenth of December, 1886. I showed him to you the next day, and I presume you have not forgotten his appearance or the train of symptoms which he presented. Lying in a state of prostration, his eyes half closed, his complexion one of complete pallor, you noticed how shallow and frequent was his respiration, how rapid, small and indistinct was his pulse, and by the head of his bed you remember there were two spittoons full of bright red blood, which had been expectorated during the latter part of the night, and especially since three o'clock in the morning. We learned that for four days he had raised blood of the same quality repeatedly and in great quantities. The blood was rusty, frothy; it had been ejected during violent attacks of coughing. There was no doubt as to his condition, the diagnosis was plain; it was a case of hæmoptysis, whose onset dated back four days, to the 12th of December.

The hemorrhage which caused the hæmoptysis certainly did not originate in the pulmonary parenchyma. Pulmonary hemorrhage indeed, whether in focus or infiltrated, gives rise to an expectoration of black, non-ærated blood, composed generally of distinct sputa. One glance at the blood raised by our patient was enough to lead us to reject this hypothesis, and I have only alluded to this contingency in order to freshen your memories.

The hemorrhage which produced this hæmoptysis, then, had its seat in the bronchial tubes; it was a bronchorrhagia, and if the blood expectorated perfectly retained the character of arterial blood, it was because it was voided as it had been effused into the bronchi. Granting this as to the seat of the hemorrhage, what was its source? From what vessels did it come? On account of its bright color it could not have come from one of the pulmonary arteries; it must have been one of the bronchial arteries, or pulmonary veins, which had given way. Between these two possibilities we could not pronounce positively from the character of the blood. We shall soon see that the study of the case will warrant a conclusion which is at least probable.

[1] Translated by Kate C. Hurd, M.D.

[2] A state of under nutrition of the lungs, insisted upon by Jaccoud as a condition existing before phthisis.

Hæmoptysis by broncorrhagia—such, then, is the symptomatic diagnosis; to this first stage of judicial inquiry should succeed the pathogenic diagnosis. What is the cause of this hæmoptysis? The prognosis, the nosological significance, in a word the medical diagnosis, depends on the reply to this question. The solution is often difficult; in order to obtain it with certainty, you should always conform to the method which you have seen me apply in the case before us. The process is as follows: 1. Ascertain the state of the lungs. 2. Determine the conditions under which the hæmoptysis appeared. 3. If the examination proves the existence of any lesion in the lungs, determine the chronological relation between this lesion and the hæmoptysis.

Our first point then is to ascertain the condition of the lungs. On examination we find the right lung sound; as for the left lung, it is equally sound in front, but behind, at the median part, a little below the spine of the scapula, in a limited area no larger than the palm of the hand, I have discovered since the admission of the patient a focus of moderate dulness and of fine sub-crepitant râles. In the next place, we want to determine the condition under which the hæmoptysis appeared. The conditions possess a strange definiteness in this case. November 12, the Sunday before his admission to the hospital, this man being in perfect health, ran rapidly for several minutes in order to overtake an omnibus; just at the moment, when, having nearly reached it, he was stretching out his arm to grasp the railing of the the omnibus, he was suddenly seized with a violent fit of coughing and immediately on the spot he raised a great quantity of bright red blood, like that which we have this morning seen in the spittoon.

By the time he had returned to his home the hæmoptysis had ceased. On Sunday evening he had a second attack, then another on Monday, and so on each day, until he entered the hospital, Wednesday, December 15. During the interval between Sunday and Wednesday, a fever set in, for his temperature on entering was 101°.3 F., the next morning, it is true, it was only 100°, but that evening it mounted to 102°.9. In fine, the hemorrhage as you see was caused by the exertion of rapid running.

The third point is to determine the chronological relation between the lesion in the lungs and the hæmoptysis. This relation is very clear. The hæmoptysis appeared suddenly while the patient was in a state of perfect health; it was then the primary incident; the lesion in the left lung and the fever are secondary effects. This inquiry brings us then to the following diagnostic conclusion: hæmoptysis following a violent muscular effort or strain in an individual whose respiratory apparatus was healthy. But this conclusion, perfectly justifiable though it may be, since it is the simple expression of the facts, is evidently insufficient; there must have existed in this man some other condition which caused his exertion to bring on a hemorrhage. What was this condition?

Must we admit a tuberculosis, totally latent until the very moment of his unfortunate run? Everything negatives this assumption. This man has never had a cough, nor has he ever had any disease of the respiratory organs; his health was in no way changed during the months preceeding the accident; and, moreover, his family antecedents are all right: his brother, sister and children are in excellent health; finally, if we found in the median lobe of the left lung the focus of râles, which I pointed out to you, weare none the less certain that the apices are quite sound. Under these conditions, latent tuberculosis is not merely improbable, it is an impossibility.

From this we are now led to the inquiry whether the condition which rendered his exertion a generator of hemorrhage may not be connected with the circulatory apparatus, although, *a priori*, the character of the blood expectorated scarcely justifies the idea of a hemorrhage of cardiac origin.

The examination shows a cardiopathy, constituted by aortic stenosis and insufficiency, with atheroma of the thoracic aorta. This evidently old lesion had never given rise to any symptom, and it was a profound surprise to the patient to see us inquiring with so much minuteness into all the circumstances of his previous history in order, if possible, to discover some cause for an affection of the heart from which he himself had never experienced the least effect. This search, however, remained of no avail, and we are still in complete ignorance as to the origin of this heart lesion, which may have been a congenital malformation.

However this may be as to the matter of causation, the lesion is there, and modifies the conditions of the cardio-pulmonary circulation in the manner most favorable for the production of hemorrhage. In fact, by this alteration of the aortic orifice, the left ventricle and auricle are kept in an abnormal state of repletion and distention. As a consequence, the pressure is constantly increased in the veins which empty into the left auricle, *i. e.*, the pulmonary veins. Let

there then be an exertion which suddenly raises this already excessive tension, and ruptures will take place in the finer radicles of that portion of the vascular system involved, that is to say, in the alveolo-bronchial plexus of the pulmonary veins.

Such is the cause, and such is the mechanism of the hemorrhage, with which this patient was suddenly seized on the occasion of his violent run. The focus of inflammation in the left lung indicates the spot at which the blood was poured out; it was the effusion which caused this inflammation in the tissue of the lung, and the symptomatic fever.

During the six days which have elapsed since the admission of the patient, we have observed favorable modifications as far as the hemorrhage and fever are concerned, but unfavorable changes in respect to the lesion of the left lung.

The hæmoptysis persisted with the same bright red appearance during the day of the 16th and the night of the 16th; there was none on the seventeenth day, but it returned in the night of the 17th, though in smaller amount, and has twice since been repeated in the night time, but it has ceased since yesterday morning. The fever fell to 100°, as you see by the tracing, but yesterday afternoon it went up to 102.°2, so that we cannot yet prognosticate anything as to its further evolution. His general state is very satisfactory, considering the symptoms from which he has suffered. There are no bacilli in the expectoration, which for twenty-four hours has been composed of dark bloody sputa, mixed with viscid mucus.

During this same interval the focus in the left lung has steadily grown larger; and this very morning I called your attention to the modifications which have supervened. Last Thursday, forty-eight hours ago, there was in an area as large as the palm of the hand only a slight dulness and fine râles; to-day the lesion has increased below and above, even to the apex of the lung, and the condensation of the tissue is notably augmented; the dulness is complete, and in all that zone the râles of variable volume are mingled with blowing breathing and bronchophony.

The elevation of temperature last evening was probably the result of this aggravation of the local trouble; what is quite certain is that we find in that one spot, ten days after the occurrence of the accident which brought him before us, a focus of pneumonia created by the hemorrhage, and that this focus was already appreciable on the fourth day, and that since then we have followed day by day its development and the modifications which it has undergone. This first phase of the case which must be clearly understood in order that you may well comprehend what comes after, is then of exceptional precision. And now the principal question presents itself: What is to be the future of this patient? We cannot tell to-day, for his destiny depends on the uncertain and variable evolution of the pneumonic *foyer*, the result of the hemorrhage.

A simple resolution is possible; this favorable termination, which implies before all a stationary condition of the actual lesion, may take place after an interval of from six weeks to three months. The pneumonic focus may persist without any extension and without change in its character, and may result in the destruction of the central portions of the lung by the continuity of the inflammation, and by elimination of the fibrinous nodules resulting from the stagnation of the blood. The observations of Thomson have called our attention to this favorable course which I have never observed. It is not, by any means, as fortunate a termination as the preceding, but it has not the irremediable gravity of that kind which I am about to indicate to you.

The lesion caused by the hemorrhage is never repaired, or is repaired only very incompletely; a residuum persists, and the condition of the patient is precisely what I described a year ago when speaking of the imperfect resolution of pneumonia. In the neighborhood of this persistent lesion the vitality of the tissue is lessened; it is in a state of *sub-nutrition*, and becomes therefore a favorable culture soil for the fixation and multiplication of the bacillus tuberculosis. Let but the microbe obtain a lodgement in these conditions, it will certainly find a suitable habitat, and the pneumonic *foyer* will be transformed into a *foyer* of bacilli.

You see here, gentlemen, a good example of phthisis from hemorrhage, and I have told you how to grasp and interpret it. This patient, then, furnishes a new instance of that form of phthisis which has been denied by some, though wrongly; and it is the more convincing from the fact that the initial hemorrhage did not take its origin in the respiratory apparatus.

March 26, 1887.—The result has confirmed my previsions. The patient succumbed March 19 to pulmonary tuberculosis, three months and one week after the first attack of hemorrhage. During that time we noted the extensive ulceration going on at the primitive focus of the left lung, the pro-

gressive infiltration of the whole of this same lung, and till the end we could testify to the perfect integrity of the right lung.

The hemorrhage was not repeated, the expectoration gradually became purulent, and from the last of January we found bacilli in abundance, although they were vainly sought during the weeks which followed the admission of the patient into the hospital.

During December, January, and the greater part of February, the fever was very irregular, often intermittent, sometimes *nil*, but from the 25th of February it became high and continuous, and remained to the end between 100° and 102°.2 F.

The autopsy has been singularly confirmatory of our diagnosis; you may convince yourselves of this by examining the specimens which I here show you.

The left lung is riddled with little cavities in all its upper half, and the largest cavity, which exceeds the size of a large chestnut, corresponds exactly with the crepitant focus noticed on the entrance of the patient, the focus which remained for a long time the only lesion. In the spaces between these cavities, and in its whole lower half, the lung is the seat of a solid tuberculous infiltration.

The right lung is absolutely healthy; it contains not a single tubercle, and presents only a slight œdema.

The aortic valves are rigid, indurated and thickened by the old atheromatous deposits which extend throughout the whole thoracic aorta.

Remember, gentlemen, the lesson which this case teaches. It shows once more the reality of phthisis *ab hæmoptoë*, and fully justifies the doctrine which I have so long taught, of pulmonary hypotrophy (subnutrition) as a cause of tuberculosis.

—According to M. Luc and some others, there exists a variety of tracheitis, associated with nasal ozæna, but which, once established, evolves independently of the latter. The tracheitis is characterized by fœtid secretions in which the microscope reveals the presence of micro-organisms similar to those found in the crusts from the nose in cases of ozæna. The scabs on the walls of the trachea do not proceed from the nose, but are autochthonous. The clinical characters of tracheal ozæna consist in expectoration, especially in the morning, of greenish sputa, thick, viscid, and exhaling the peculiar odor of ozæna, and the persistence of the fœtor of breath after thorough cleansing of the nasal fossæ. Laryngoscopically, the crusts may be seen on the walls of the trachea.—*Lancet*, March 24, 1888.

Communications.

Ovariotomy.

BY R. STANSBURY SUTTON, M.D.,
PITTSBURGH, PA.

It has been stated that to offer anything further upon this subject one should offer an apology for so doing. It is not so, else all who are interested need nothing more. The doing perfectly, every time, of any one operation is rarely the gift of a surgeon. We all operate much as we feel—well to-day, indifferently to-morrow. Surrounded to-day with favorable conditions, to-morrow with unfavorable conditions. To-day with skilled assistants; to-morrow with assistants who have no dexterity, or experience upon which to attempt any. To-day with a case sent early for operation; to-morrow with a case which has been the subject of the most brutal ignorance, trocar-marked from ensiform to pubes, her physical powers exhausted, and her sorrowful poverty somewhat to be accounted for by faith in drugs. So long as "absorbtion" is advocated as a remedy, so long as the brutality with the trocar continues, so long as women are urged to "wait until you must be operated on;" so long as all are not familiar with the operation itself, and all of its favorable and unfavorable surroundings, its elements of success and failure—so long we should continue to write and abjure apologies for so doing.

The obstetrician teaches first the mechanism of normal labor, subsequently the mechanism of difficult labor. It is the natural order. The young obstetrician is a success; the majority of labors are natural labors. The management of these gives him confidence, and when he advances to the difficult cases he is prepared to succeed. No one says to him let that woman alone until the angel of death is at her door and then aid her, but all say go! examine, give proper attention, aid her until delivered. When such action shall be the rule with women suffering with intra-abdominal cysts few will die, not more than die in childbed. Normal labor and early ovariotomy may be equally successful. Often men report, as I have done, their failures and success, some their success only. Few report their cases with the sole object of doing good to humanity; I do not claim that I do, if I did I would not be believed, perhaps properly so. But in giving the following typical case of a simple ovariotomy, I claim these objects, viz., *to teach those who desire to be taught the importance of early ovariotomy,*

its simplicity and its glorious triumphs, and to warn those who oppose the operation, and who maltreat these defenceless patients through their deplorable ignorance or woful stupidity.

Case 64.—April 30, 1888, Miss W., Pennsylvania, a stranger to me, aged 32, unmarried. On examination presents a multilocular ovarian cyst. Nothing excepting her size obstructs her daily duties. She is a feeble woman by nature. An examination of three minutes' duration without any instrument whatever established the diagnosis. Her period is due in two days, May 2.

May 2d to 6th menstruated.

May 8th, she entered my private hospital, 8 P.M., and had a full hot-bath.

May 9th, A.M., a dose of purgative (compound liquorice powder); light diet throughout the day.

May 10th, A.M., breakfast of soup, bread and coffee; no dinner. Etherized in bed and conveyed to the adjoining room for operation at 2 P.M.

Present, Drs. Williamson, Huselton, Davis, Lindley, Blackley and Dodds.

A four-inch incision, without the aid of grooved director, was completed in ten seconds. A large trocar rapidly reduced the cysts, which were delivered long before they were empty. The pedicle which was short and broad was tied, cut off and burnt, and two minutes and thirty seconds more time had gone.

The second ovary, which was diseased, was removed and its stump seared with the Paquelin; by this time not quite five minutes had gone. Two pitchers of warm water were poured into the cavity of the abdomen and sponged out, the sutures were introduced and tied and the wound closed, all in eighteen minutes; weight of cysts and contents fifteen pounds. On the following day pulse 96, temperature 99½° F. On the second day pulse 90, temperature 100° F. On the third day pulse 84, temperature 98½° F. On the fifth day stitches all removed, wound entirely healed, appetite and sleep normal, and the patient left to the nurses.

Such is the history of operations in simple cases, cases operated upon early. If this simple lesson will help the cause its aim will have been accomplished.

—The nineteenth annual session of the Medical Society of Virginia will be held in Norfolk, Tuesday, October 23, 1888. Upon the Society devolves the duty of appointing the thirty-two members of the Medical Examining Board.

HYPODERMIC USE OF NITROGLYCERINE IN HEART FAILURE.

BY M. HOWARD FUSSELL, M.D.,
PHILADELPHIA.

The results of the hypodermic use of two drops of a one per cent. solution of nitroglycerine, in the following cases of heart failure, were so satisfactory that it seems a matter of importance to the writer to place them on record.

Case 1.—Mrs. G., aged 63, subject to dyspnœa, palpitation and recurring œdema for several years, had a slight cerebral hemorrhage two years ago. Examination at that time showed disease of the mitral valve. Under treatment with digitalis and strophanthus, the case progressed favorably until January, 1888. Suddenly on the night of January 2, the patient, after having passed an unusually good day on the first, was seized with urgent dyspnœa, so that she was unable to lie down, and she became so sick that I was summoned about 3 o'clock in the morning. I found the patient unconscious, both her lungs full of bubbling râles, her pulse ninety and weak, but remarkably regular considering the patient's general condition. Her breathing was stertorous, and could be heard in the next room.

The patient having previously had cerebral hemorrhage, I at first thought this attack was a recurrence of the same trouble; but the fact that there was no recognizable paralysis caused me to doubt this diagnosis. The patient's condition was so bad, however, that I told the family she was the subject of heart failure, and in all human probability would die in a short time.

At this juncture I remembered a remark made to me by Dr. John H. Musser, of West Philadelphia, to the effect that he was certain he had in such cases saved life, at least temporarily, by hypodermic injections of amyl nitrite.

The patient had been taking nitro-glycerine before the attack, so I procured the bottle, gave a hypodermic injection of two drops, and retired from the room to await the death of the patient. In just twenty minutes from the time of the injection the attendants called out that our patient was dying. I went into the room, and, instead of finding her dead, saw that she had raised herself in the chair in which she was propped, and was evidently conscious. I spoke to her and received an intelligent answer. Her pulse had become still more regular than it had been before, and her breathing less

labored. I immediately repeated the injection of nitroglycerine, and in the course of an hour had the satisfaction of seeing my patient's condition so much improved that she was able to talk and could lie down without trouble, while the râles had disappeared from all parts of her chest, except the extreme bases of the lungs. In a few days the condition of the woman was quite as good as it was before the attack, and she was able to go about the house comfortably.

Case 2, was one of typhoid fever. The patient, a man 45 years old, had had a remarkably light attack of fever, his temperature never rising above 102°, and by the end of the second week it had reached the normal point.

On the sixteenth day of the disease the patient awoke in the morning saying he felt better than he had felt on any previous day. Notwithstanding the repeated warnings he had received not to make any undue exertion, he arose suddenly from his bed, reached under it for the commode, and immediately fell back in a faint. I was sent for, and on my coming found the patient in a deplorable condition. His pulse exceedingly irregular and weak, and so rapid that it could not be accurately counted; his face cyanosed; his hands and feet cold; his lungs full of râles. I immediately administered two drops of nitroglycerine hypodermically, and applied heat externally. In a few minutes I had the satisfaction of seeing my patient's condition begin to improve. His pulse became more regular, though still exceedingly rapid, and his breathing less labored. Stimulants were then administered, and he gradually improved for two days, when death took place from another attack of heart failure, following a persistent straining at stool.

Case 3.—A man, 59 years old, an habitual drinker, and the subject of mitral disease of the heart. After retiring on the evening of May 1, he was suddenly attacked with urgent dyspnœa. He arose, was propped in a chair, and tried vainly to obtain relief from his oppression. I saw him one hour after the beginning of his attack, and found his pulse irregular, rapid and weak. His breathing was rapid, his face cyanosed, and his lungs filled with bubbling râles. He was conscious, but unable to speak connectedly. Remembering my former success with nitroglycerine, I immediately injected two drops hypodermically. This was followed in a few minutes by marked relief. In half an hour I injected one drop. At the end of three-quarters of an hour the patient's pulse was regular; he could talk easily; his breathing was almost normal. I then ordered whiskey and digitalis to be given during the night, and in the morning found him exhausted, but almost in his normal condition.

In all of the above cases death seemed imminent. In the first case the woman would certainly have died very soon had she not received prompt relief. The treatment by the hypodermic use of nitroglycerine acted so promptly that the bystanders were very much impressed, and the physician was almost as much astonished as they were.

I have treated similar cases with stimulant hypodermics of whiskey and digitalis, but sometimes death was not averted, and when it was the relief was long delayed.

One who has seen cases of heart failure treated in the usual way can have no conception of the brilliant results which may be obtained by the hypodermic use of nitroglycerine. The treatment has the great advantage that it is harmless in any event; and I believe it should always be tried, though, of course, not to the exclusion of other well-known methods of relief.

SPINA BIFIDA.

BY SAMUEL WOLFE, M.D.,
SKIPPACK, PA.

On the 18th of March, 1888, Mrs. B., aged 27, was delivered of her second child. The size, weight and general appearances of the child presented nothing peculiar. Over the spine, in the dorsal region, extending downwards, from a little above the middle of that region, for three inches, with a breadth of two inches in its widest part, was what appeared to the eye a raw patch, looking very much like a gaping incision through the skin, in a muscular region, which had become somewhat glazed by having been left undressed, after having been thoroughly cleansed. The ends of the patch tapered from a sharp point above, to a more obtuse termination below. Several longitudinal streaks of yellowish-white traversed it from above downwards. At several points there was the very slightest oozing of blood, and a high degree of injection of very small vessels. Along the lateral edges of the patch could be felt a row of bony, obtuse points.

The frontal bone was incomplete to the extent of two fingers'-breadths, from the anterior fontanelle to a level with the frontal protuberances.. The parietal bones did not meet within one finger's-breadth. Over the lines of the other sutures there was less, but

still undue separation. There was very slight bulging of the skin in the region of the frontal deficiency, but the size of the head was normal, with no evidence of accumulation of fluid within the cranial, or rather meningeal cavity, unless the slight bulging, already noted, might be thus regarded. The limbs were well developed and well shaped. The spinal defect was dressed with ung. zinci oxidi. Within thirty-two hours there were evidences of healing from the edges of the raw surface, and the dressing was continued. About the fifth day a yellowish membrane had formed over the surface, and there was active secretion of pus. The surface was cauterized with argent nit., which apparently gave no pain whatever. This line of treatment was continued throughout, and the healing action under it made progress. On the third day the slight bulging in the frontal region had receded. During the fourth week the head began to enlarge, with all the characteristics of hydrocephalus, slight convulsive twitchings occurred, the strength began to fail, the flesh to waste, and just before having completed the fifth week of life, it died of exhaustion. The spinal affection had not materially changed. During the first three weeks the heart had been normal in its action, the bowels and kidneys acted regularly, the child nursed well, and in every respect the condition was thriving. During the last two weeks the lower limbs became contorted by tonic contractions, twisting the feet somewhat inward and upward. With the aid of Mr. J. N. Hunsberger, my student, I dissected the affected spinal region, finding the coverings, though with difficulty separable and distinguishable, to represent skin without epidermis, dura mater, and arachnoid. About a half fluid drachm of pus escaped when the inner covering was incised, and with it a white cord about one inch in length, and resembling a nerve of medium size in thickness, and of a consistence much softer than a normal nerve, flattening under pressure between finger and thumb. This was all that was found to indicate the presence of the cord, and it escaped with the pus in such a manner as to seem to have had no attachment. Of bone, there was absolutely nothing but the bodies of the vertebræ, which were held together by a tissue resembling in position and strength the posterior common ligament. There was some arching backward. The bones involved were the five lower dorsal and two upper lumbar vertebræ. Downwards, no trace of a spinal canal could be found; upwards, its calibre was very small and apparently tortuous, but as the dissection was not carried beyond, I can give no more details besides stating that the external appearances in the rest of the course of the spinal column were normal.

As to the family history, the mother had one year and two months before given birth to her first child, which was similarly deformed as to the spine, except that the affection was then located lower down, entirely in the lumbar region. There was also talipes in that case. No defect in skull, but general condition feeble. The child died on the third day after several convulsive spasms. No post-mortem was made. The mother is a healthy woman. The father also in good health. One of his brothers died in infancy; he does not know of what disease. A sister was temporarily insane at the age of 20, the cause apparently having been disappointment in love. She was afterward restored, married, had six children, and committed suicide by hanging at the age of 40.

The literature on the subject of spina bifida seems to be comparatively meagre, but from all I can find the above case has but seldom had its analogue amongst those reported. The position of the affection is almost constantly in the lumbar or sacral regions.

The skin is in all cases, so far as I can find any record, normal, or simply thickened, or thinned or discolored. There is always bulging, forming a tumor of the size of a walnut to that of an orange, and frequently much larger. There is always a collection of fluid (cerebro-spinal). In this case there was none. The advancing hydrocephalus did not affect the spinal disease, indicating that no direct communication between spinal and cranial cavities could have existed. The remarkably small quantity of nerve substance found, was also peculiar. The cord in many, probably most cases, presents little abnormality, except the effects of pressure or adhesions.

The theory of Lowne, that excess of cerebro-spinal fluid is the active factor in the causation of the disease, will not apply here, and I may venture the suggestion that even in the ordinary, typical cases, the excess of fluid is due to the want of resistance, from the imperfect formation of the osseous canal, rather than the latter an effect of the former.

The one practical lesson, which I draw from these two cases, is, that when the mother again becomes pregnant, I will administer during the entire period of gestation, such drugs as are calculated to stimulate the bone-forming forces, and to administer in the shape of food, cod-liver oil and lime salts, a pabulum for such forces to act on. It might even

be justifiable to put both parents on a suitable regimen, previous to the occurence of conception.

CREASOTE IN PHTHISIS.

BY FREDERICK L. LADUE, M.D.,
ALBURGH SPRINGS, VT.

While fully realizing that the termination of any one case after treatment by a method not thoroughly established is an insufficient criterion of the merits or demerits of any new departure in therapeutics, yet I am convinced that in such a formidable disease as phthisis pulmonalis the profession is not averse to having their attention drawn to a favorable report of a case treated with drugs but little used, no matter how irrational or empiric their use may be, provided only that they promise help in the stern battle with that insidious foe, tuberculosis. Probably in no other common disease has the profession evidenced so much avidity to grasp at empirical, undemonstrated and unscientific methods, as in the disease in question. This results undoubtedly from our utter helplessness when face to face with the disease in its later stages. The recent craze for rectal injection of gases is testimony for this statement.

Since the announcement of the bacillus theory of phthisis the line of investigation has materially changed, and where once the only fight was on the defensive—repairing the damage done by the silent enemy—now the base of attack is changed, and the grand charge is tending toward annihilation of the enemy itself. Medical men exhibit a strange inconsistency between their belief and their actions. While thoroughly believing and accepting the theory of Koch and learnedly talking and writing of germs and microbes, yet they make no pretense to the destroying of the germs themselves. Valuable time and valuable lives are wasted in temporizing with the old modes of treatment which, while good so far as they go, fall short of the mark set up by Koch. If we are to accept the germ theory—and microscopy says we must—then why not try antiseptics and germicides? Experience has fully demonstrated the fallacy of our old methods of treatment. One-seventh of the entire population falls a victim of this disease, showing conclusively how futile are our powers in the face of this scourge.

Doubtless it was by this or similar reasoning that Sommerbrodt, whose name may yet be placed with Koch's, resorted to the use of creasote. This well-known germicide has been demonstrated by Sternberg to be fatal to micrococci in the strength of 1 to 200. While Sommerbrodt admits that it may not be from its antiseptic or germicidal powers that it benefits, but that it may be simply from its favorable action upon digestion, still he advises that it be pushed to its utmost limit of toleration, as here is where so many fail in its use. Pushing it to this extent would be unnecessary if its beneficial action was expended only upon the process of digestion and assimilation; for experience with the drug plainly shows that it is the small doses and not the large which assist digestion, and that the large ones which he advises occasionally irritate the stomach. He says that disappointment arises only through timidity. "The more creasote that can be borne the better the effect," is his dictum. He claims to have treated 500 cases during the past nine years, and of those treated by Bouchard's formula, 27 per cent. recovered. Others were treated by the following formula, which gave the best results:

℞ Creosoti.....mxv
Tr. gentian.....mxlv
Spir. vini rect.....fʒviss
Vini Xerici q. s. ad.....fʒiij

Of this one ounce was taken three times a day. The creasote was gradually increased to thirty grains. He obtained the best results by following treatment for from three months to a year. The most benefit was seen in the young and in the first stages of the disease, when the symptoms were not well defined. Good results were always secured when scrofulous glands were present. It generally relieved irritation and cough, and secretion and expectoration diminished, so that narcotics could be dispensed with.

Dr. J. Solis-Cohen has used creasote for many years, not as a specific but to prevent retardation of the decomposition of undigested nutriment. He has used it in chronic diarrhœa for twenty-five years. He has found that the beechwood creasote is the best to use, and rarely exceeds one-half minim at a dose. He claims to have used this with such benefit for twelve years that he rarely uses oil or hypophosphites.

Mrs. G. M., thirty-six years old, was seen first for her present trouble, December 3, 1887. I had treated her four years before for incipient phthisis, but had heard nothing from her during the intervening time. On November 1, one month before I saw her, she gave birth to a child, and since her confinement had rapidly failed until she sank into a condition of tuberculosis in the third stage.

Her condition was as follows: Temperature 103°; profuse sweating at times; violent cough and abundant expectoration of yellow mucopus; violent delirium occasionally, but never quite herself. Physical examination disclosed the fact that there were large cavities in the apex of the left lung and flatness upon percussion in other portions of the same lung. Auscultation showed the vesicular murmur absent in the apex of left lung, and the presence of blowing, gurgling respiration with bronchial breathing in other parts. The pulse was 120: there was no appetite. I immediately began the use of creasote, giving one minim three times a day, and gradually increasing drop by drop until the amount of thirteen grains was taken (January 14, 1888) at a dose. At that date the delirium had entirely disappeared, sweats greatly diminished, cough slight, and little if any expectoration. She has gained strength, flesh and appetite. She sits up four hours a day, whereas ten weeks ago she could not get out of bed. At the date of present writing, May 1, she is around the house, gaining flesh and feeling well. The lungs have improved, and the gurgling sound of air bubbling through fluid is gone. She has taken creasote constantly for four months with two interruptions of one week each. She has taken as high as eighteen grains at a dose without visible inconvenience. During this time she has had no other medication, and her diet has been principally composed of crackers and potatoes. I should state, however, that she had small quantities of whiskey part of the time.

—M. E. Beaupère, basing his opinion upon twenty-six observations made for the most part in the service of M. Levrat, at the Charity, concludes as follows:

Chloroform is indicated for the performance of tracheotomy in children attacked with croup. It acts in small doses and rapidly, without provoking in most cases the period of excitation. It does not increase asphyxia, it stops laryngeal spasm, and renders the operation more easy by making the child immovable and by the absence of congestion of the veins of the neck. Far from predisposing to syncope, it can, on the contrary, prevent it by diminishing inhibitory susceptibility of the region. Its use does not influence the subsequent evolution of the diphtheria. It enables one to dispense with several assistants. The only contra-indications to its employment are advanced asphyxia or lesions of the lungs. —*Bulletin Médical*, April 15, 1888.

AMERICAN MEDICAL ASSOCIATION. —SECTION WORK.

Third Day, May 10, 1888.

SECTION ON DISEASES OF CHILDREN.

Dr. D. A. K. Steele, of Chicago, read a paper on

The Surgical Treatment of Empyema in Children.

In the consideration of its surgical treatment we must remember the surgical maxim that "wherever we have a pus collection it must be evacuated in the speediest, safest, and most thorough manner." In the majority of cases it is my belief that a purulent pleuritis is due to auto-infection of a more or less limited area of the inflamed or damaged pleura through the medium of the general circulation; the pus microbe thereby gaining entrance and commencing its destructive action upon tissues which otherwise would only be the seat of a simple pleuritis. Other methods of infection are the use of unclean aspirating needles; rupture of the bronchus; extension of a septic pneumonia; secondary infection from the primary foci in some other point of the body; tubercular infection, etc. Empyema, if left to itself, may terminate in recovery in one of three ways according to L. Emmet Holt—(1) by spontaneous absorption of the purulent effusion; (2) by evacuation through the bronchus; (3) by opening externally through the intercostal muscles; but when left to nature the mortality is appalling. Rilliet and Barthez mention 33 cases, with 4 recoveries, 21 deaths, and 8 not accounted for.

In regard to the surgical treatment, no absolute rule can be laid down for the management of all cases. We have our choice of operations from the following: For example, we may resort *first* to aspiration; *second*, aspiration and washing out of the cavity with an antiseptic solution; *third*, thoracentesis with trocar and canula; *fourth*, thoracentesis with sub-aqueous drainage; *fifth*, simple incision; *sixth*, simple incision and drainage; *seventh*, simple incision with through and through drainage, with or without antiseptic precautions; *eighth*, subperiosteal resection of rib and drainage; *ninth*, thoracoplasty (Estlander's operation); *tenth*, perflation. Each of these various methods will give good results. As a matter of fact, as practical surgeons, we may confine ourselves to the relative merits of but two of these methods—aspiration and

free incision with drainage. There is no question but that in a certain minority of cases in children, simple aspiration once or twice repeated, will effect a permanent and satisfactory cure. Aspiration has the advantage of being simple, safe, and occasionally curative; but if we find the fluid really accumulates, or septic symptoms are developed, then a free incision with drainage is imperatively demanded. Aspiration has the disadvantage of leaving a small amount of pus for reabsorption, or which may become an inspissated residuum that will result in a secondary abscess in after life. Surgically considered, it is not as perfect an operation, or as scientific a procedure, as evacuation by free incision and the introduction of a large-size drainage-tube. Of 121 cases treated by aspiration alone, 23, or 19 per cent., were cured, six died, and the rest came to some other treatment, usually incision. In regard to Ewart's method of perflation, reported last year, I have no personal experience.

In conclusion, therefore, I may summarize my observations as follows:

(1) The surgical treatment of empyema in children is eminently satisfactory and yields better results than in adults. (2) Multiple hypodermic aspirations are necessary to perfect a diagnosis, and should always be resorted to in cases of thoracic disease about which there is any element of doubt, especially in cases of pneumonia that exceed the usual period and become "old-monia." (3) Aspiration cures a small minority of cases and should always precede a more radical operation, especially in localized empyemas. (4) Free incision and drainage, with local anæsthesia, under strict antiseptic precautions, gives the most satisfactory results in the majority of cases. (5) Subperiosteal resection of the rib is sometimes necessary to afford perfect drainage. (6) Thoracoplasty is rarely required in children. (7) Other methods of treatment should be resorted to for special cases or circumstances. (8) Early incision, perfect drainage, and complete antisepsis should be the rule.

SECTION ON OPHTHALMOLOGY, OTOLOGY AND LARYNGOLOGY.

The session opened with a paper by DR. E. FLETCHER INGALS, of Chicago, on

Naso-Pharyngeal Fibromata.

He reported four cases to the section in 1884, two of which had been cured, and two of which had disappeared. He advocated the extirpation of these growths, when possible, through the natural passages by means of the galvano-cautery ecraseur or other methods employed by laryngologists in the destruction of nasal polypi, in preference to the formidable operation, including removal of the superior maxilla, which has frequently been practiced by surgeons and which is still believed by some to be the best means of eradicating such growths.

Dr. Lincoln, of New York, had shown that the operation usually adopted by surgeons was extremely hazardous, over twenty-five per cent. dying from the operation, while it was not very successful in preventing recurrence, as in only about fourteen per cent. was it certain that the tumor had not returned within a year, while by the method which he then recommended it was shown that the danger to life was very much less and that the ultimate results were much better, as in over fifty per cent. recurrence had not taken place within twelve months. Recently, one of the cases then reported, which had failed to return after the first sitting for completion of the operation, and which he had lost sight of at the time his paper was written, had returned after the lapse of five years with a renewed growth in the same locality. This was removed by means of the galvano-cautery ecraseur. The operation was done after the parts had been anæsthetized by cocaine, and was completely successful in removing all the tumor, which consisted of three lobules which had been attached by a base about half an inch in diameter at the vault of the pharynx and posterior nares of the left side. The tumor removed five years ago had the appearance of being composed entirely of fibrous tissue. Of the tumor recently removed, the smaller lobules, which measured about five-eighths of an inch in diameter, proved upon microscopical examination to be made up of fibrous tissue; the next larger lobule, which measured about three-eighths by one-half inch, appeared to be fibro-cellular in character, about one-half fibrous; and the largest, which measured about one by two inches in diameter seemed also fibro-cellular, about three-quarters fibrous.

He had also to present to the section the history of a case and the specimen (a large fibrous growth) recently removed from the nasal pharynx with the galvano-cautery ecraseur.

The patient, W. K., aged sixteen, for two years had been troubled with difficulty in breathing through the nose, and frequent epistaxis. For about two months before consultation he had suffered from frequent alarming hemorrhages, during one of which his attending physician had been called in for the first

time. The doctor checked the hemorrhage, but the patient was much exsanguinated and in no condition for an immediate operation; therefore he was placed upon tonics and nutritious food and given time to recuperate. Dr. Ingals found the patient well nourished and with no appearance of anæmia. His voice was of that peculiar character known as nasal; the sense of smell was nearly lost, and he complained of pain in the side and back of the head. The left cheek over the lower maxilla was quite prominent and apparently swollen, but there was no induration excepting just opposite the posterior molar of the upper jaw, where a conical tumor could be felt deep in the soft tissue. This tumor appeared to be about five-eighths of an inch in diameter at farthest point where it could be felt, which was about the same distance back of its apex, and it was evidently attached far back in the tissues out of reach. Upon examining the nares anteriorly, the posterior third of the left cavity was found filled with a firm growth of a light pink color, which bled very easily on being touched with a probe. Examining the mouth, the soft palate was seen to be crowded downward, and rhinoscopic examination discovered the naso-pharyngeal cavity to be filled with a firm tumor of a light red color and smooth surface. The slow progress of this case, the frequent attacks of epistaxis, and the appearance of the growth itself, convinced Dr. Ingals that it was a fibroma. He recommended removal by the galvano-cautery ecraseur and left the patient to decide whether it should be done under the influence of cocaine or ether. On the afternoon of the same day he operated. A ten per centum solution of cocaine was first applied to the nasal pharynx and left naris, by means of an atomizer and syringe, about once in two minutes for fifteen minutes until the parts were insensible. He then passed through the left naris two catheters which were brought out of the mouth, and though these were passed the two ends of a number eight platinum wire, and these were drawn out of the nostril with the catheters; the loop was carried up behind the tumor by the fingers; the ends of the wire were then passed through a tubular electrode and made fast to a rachet on the handle, and the battery was connected. He now tightened the loop by turning the rachet and then heated the wire for two or three seconds by closing the circuit; then allowed the patient to rest a few seconds, and then repeated the procedure, thus alternately heating the wire as long as the patient could easily bear it and then allowing it to cool, and, tightening the rachet, he soon burnt off the growth at its base, which was more than an inch in diameter. The tumor was removed through the mouth and proved to be a hard fibrous mass, measuring one and three-eighths by two inches in diameter, and one inch in thickness. During the past three years he had operated on two other cases of naso-pharyngeal tumors which appeared at first to be simple fibromata. The first case, A. B., aged thirteen, was brought to him from Dakota, and during the course of a year and a half underwent three distinct operations, in each of which the tumor was removed as thoroughly as possible, but a small portion of it, which was doubtless left in the tissues about the pterygoid process, could not be extirpated. The late Professor Moses Gunn at one time removed a tumor, which was about an inch in diameter from this patient's cheek. During the last six months of the treatment the tumor grew so slowly that he hoped for its complete destruction.

The second of these cases, E. J., aged about 13, was brought to him from Nebraska, about two and a half years ago, with a fibrous tumor which filled the left naris and naso-pharyngeal cavity. In this case the tumor was removed partly by the galvano-cautery and the steel wire ecraseur, and partly by cutting forceps. There was profuse bleeding whenever the cutting forceps was used, but it was readily checked by tamponing the nasal and naso-pharyngeal cavities with a strip of gauze, saturated with a mixture of tannic and gallic acids, which had been rubbed up with just enough water to make it the consistence of syrup. The record of the case has been lost, but three or four operations were done at intervals of from three to five months, each time the growth being removed as completely as possible, part of it having penetrated the surrounding bony structure. The last operation was done about a year ago, and he has not since heard directly from the patient, but from another patient who knew of the case, he has recently learned that the boy is living, and, that so far as the friends can tell, the growth has not returned.

Dr. Ingals believes that all of such cases which afford any hope of cure should be operated upon through the natural passages. When the growth has been removed, if any parts remain which are inaccessible to the ecraseur, cautery, knife, or cutting forceps, they should be treated by electrolysis, and thus even if we fail to eradicate the growth at once we may hope to prolong the case to the period of adolescence, when nature seems to set a limit, at least, in many cases to the further

development of these growths, and then a cure will be effected.

SECTION ON MEDICAL JURISPRUDENCE.

DR. DANIEL R. BROWER, of Chicago, spoke of

The Medico-Legal Relations of Hysteria.

The close relation hysteria bears to insanity makes the question of the legal responsibility of its victims often exceedingly doubtful. Under the overwhelming impulse of a perverted nutrition these patients may commit murder, incest, or other crimes. Under the domination of disordered imagination, they may make accusations of pretended assaults upon their persons, and a variety of other crimes; or they may justly claim recompense for the development of this abnormal condition of the nervous system as a consequence of the shock of railroad and other accidents.

Hysteria is a *psycosis*, the primary derangement being in the higher cerebral centers. The lower centers of the brain, the spinal cord, the sympathetic nervous system, are only secondarily affected. It consists essentially of a depressed condition of the intellectual and volitional areas of mental action, and an excitation of the emotional and perceptional areas. This condition of mind produces a defective will power; an imperfect self-control; an insatiable craving for sympathy; an exceedingly irritable and irascible disposition, and with this is very often associated sometimes as an inheritance, sometimes as an outgrowth of this unbridled emotional condition, a defective moral tone, and sometimes an unnatural and ungovernable activity of the sexual system.

The morbid excitement of the sexual organs of these hysterical patients sometimes places them in medico-legal relations. There are many examples in the annals of medical jurisprudence of women who prostitute themselves without reference to the social condition of the man. Charcot furnishes the case of a young Austrian noble-woman of great beauty, who offered herself to every man, even to the lowest street character. She gave birth to a child which she subsequently decapitated without appreciating at all the nature of her criminal act. To this class of cases belong, at least, some of the cases of pretended assaults in physicians and dentists' offices.

A patient who was under my treatment for various manifestations of hysteria was sent by me to a certain distinguished specialist in gynecology in Chicago for local treatment. She made several visits to his office and a few days after the last visit sent for me. She told me that the specialist had committed an assault upon her while giving her treatment, and that, as a consequence, she had missed her menstrual period and was now pregnant. She indulged in the most violent language possible, and her husband and mother were inclined to believe her story; and had it not been for the reputation of my distinguished friend, I might have also given some heed to her story. After a few days, however, her menstrual period recurred and thus destroyed the principal foundation upon which she built her theory of assault. Had her menstrual period not returned, or had the specialist been a man of less reputation, a scandal, at least, might have been perpetrated. In my opinion gynecologists, who make examinations and treat such patients in private, are constantly in danger of such accusations.

To this same order belongs certainly some of the cases of beastly and brutal crimes committed by men, such as violent assaults upon children, and inversion of the sexual function. The case of Lord Clinton, in London, is an illustration; and in the annals of our own (Chicago) courts and those of other cities, arrests are not infrequently made for violence of public decency. Men dressed, for example, in women's clothes soliciting other men for purposes too vile to mention, are, at least, associated very often with this hysterical condition of the nervous system.

Another important legal relation of hysteria is that which grows out of railroad and other injuries. It is a well-recognized fact that nervous shock, from whatever cause it may originate, will develop the hysterical condition in those who have any tendency thereto, and strong and healthy men and women have been time and again reduced by such causes to a state in which all control of the emotions and of the will power is well nigh gone; "who cannot sleep (see Page on Injuries of the Spine and Spinal Cord, p. 172), because he has before his mind the ever-present sense of the accident; who stirs at the least noise; who lies in bed almost afraid to move; whose heart palpitates whenever he is spoken to, and who cannot hear or say a word about his present condition and future prospects without bursting into tears." We know very well there are some who regard this set of symptoms as a mere assumption, but we have had sufficient experience with similiar cases, without any legal relations whatever, in which this hysterical condition has been developed, and in which the life

has been made miserable; the usefulness of the patient diminished, if not entirely overcome—sufficient experience to know that there are some cases in which shock to the nervous system does develop, without question, this condition, and make such patients entitled to as much compensation as if they had broken an arm or fractured a skull. Indeed, the award of damages in such cases should be vastly more liberal, because the usefulness of their lives in the future has been vastly more curtailed than could possibly result from any such injury as we have described. And these symptoms of nervous disturbance in such cases are doubtless exaggerated by the long and tedious process of litigation by which the settlement is reached; and it is not surprising that when the relief comes from the adjustment of the suit and the awarding of the damages, that the satisfaction which arises from this fact, and the ease and comfort of mind which follows, bring about a disappearance of all the symptoms complained of.

SECTION ON DERMATOLOGY AND SYPHILOGRAPHY.

Dr. H. J. Reynolds, of Chicago, reported the following

Case of Nævus.

J. E. H., 10 years old, native of Minnesota; American parents; father healthy, mother died of inflammation a few days after the birth of the child, who is the subject of this report. The child has had ever since birth a thick, fleshy, prominent purplish colored growth, extending from a little below the left knee up to above the crest of the ileum. The growth encircles the lower part of the entire leg, except a narrow strip on the inside. Viewed anteriorly it recedes, extending from below up slightly to the left, so that the inner margin of the upper part reaches above the anterior superior spinous process of the ileum; posteriorly above the buttocks it extends slightly beyond the median line to the right. When first seen, some three months ago, the growth was traversed over almost its entire surface by numerous deep furrows. He has always been troubled with a very profuse serous sort of discharge of a very offensive odor, so much so in fact, that he was deemed unfit to be in school with other children. Owing to the maceration and irritation caused by the discharge or moisture, the growth was in places attended with more or less irritability or soreness. Portions of the surface of the growth are covered by a hard, scaly sort of substance, resembling somewhat an aggravated ichthyosis; long delicate hairs were distributed more or less scantily throughout the entire affected region. Another interesting feature in this case is the fact that the affected leg is about two inches longer than the other one; otherwise the child has always been healthy.

He had been treated more or less by various physicians, but never received much benefit. I ordered the part carefully washed once a day with soap and warm water, and impalpable boracic acid applied three times a day. I have not seen the patient since; but the following extract received in a letter from his father a short time ago explains itself. He says: "In regard to my son, whom I brought before you on February 8, I can say that your treatment is the best remedy I have heen able to find yet. The offensive odor and discharge have almost stopped, and the thickening is growing thinner in places, and the limb is in better condition than it had been since he was born, or since I have been paying close attention to it."

Favus of the Forearm.

The following case is deemed interesting chiefly on account of its very unusual location:

Occurring upon the scalp, tinea favosa is a somewhat rare disease, and extending from the scalp to the non-hairy skin of the same individual is a still more rare occurrence, but to develop exclusively on the non-hairy skin is a circumstance not very often met with.

M. L., 7 years old, of Jewish parents, and otherwise healthy, presented herself for treatment April 7. Examination revealed a roundish patch of eruption about three-quarters of an inch in diameter on the flexor surface of the forearm about the region of the junction of the middle and lower thirds. Exactly in the center of the patch was a bright yellow, sulphur-colored, umbilicated crust one quarter of an inch in diameter, with a crack across its centre, showing its brittle character. By carefúl examination three or four beautifully defined smaller cups about the size of the head of a pin could be observed here and there over the patch, otherwise the remainder of the patch was to all appearances identically that of ordinary ringworm, with a reddish, slightly elevated abrupt margin, with a center tending to become paler, and covered slightly with fine scales. Examination with the microscope showed the crust to be composed entirely of favus spores; scales from the reddish margin contained principally mycelia with a few smaller spores, which, as far as I was capable of judging, were identical with those found in ringworm.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, May 3, 1888.

THOMAS M. DRYSDALE, M.D., in the chair.

DR. JOSEPH PRICE reported a case of

Typhoid Fever Following Ovariotomy.

Mrs. E. N., 37 years old, one child sixteen years ago; one miscarriage fourteen years ago. She complained since her miscarriage of great pelvic pain, etc. She was operated on at the Gynecean Hospital, February 11, 1888, for the removal of the right uterine appendages. The tube and ovary were firmly adherent to and under the fundus uteri. The ovary was enlarged and cystic. The removal was not difficult and the operation was completed in twenty minutes. Two years previously the left appendages were removed for a small inflamed and adherent ovarian cyst, the right side at that time appearing perfectly healthy. The recovery from this first operation was speedy, and for a year the patient seemed in perfect health. Then the symptoms of pelvic trouble returned and were referred to the right side. From the second operation, the patient reacted perfectly, and for nine days her temperature constantly remained above normal, varying from 98°.6 to 100°.1; the intermissions never amounting to one degree. During this time she also complained of a good deal of headache, weakness and mental depression. The evening of the ninth day her temperature ran up to 102°, and she had a slight rigor. From that time she presented a typical case of typhoid fever, including the characteristic temperature record, stools and eruption. The nervous symptoms were not especially marked. The temperature varied from 99°.8 to 104°.8 for four weeks. The patient made a good recovery, and is now in better health than before the operation.

Three points of interest in this case are: 1. That the patient was probably in the early stage of typhoid fever when she entered the hospital, there having been no case of typhoid in or near the hospital at the time. 2. The operation did not seem to influence the course of the fever, nor the fever the result of the operation. 3. The temperature combined with the early constipation and meteorism were naturally attributed to the operation and treated accordingly, until the diagnosis of typhoid fever was made, after which the usual expectant treatment for that disease was pursued.

DR. J. M. BALDY reported a case of

Hysterectomy, followed in four Months by Ovariotomy and again in six Weeks by Abdominal Section for Purulent Peritonitis.

Mrs. P., 40 years old, colored, came under my care on the seventh day of last November. She had for years been suffering more or less discomfort from an enlarged abdomen. However, until within the year past she had managed to get along very comfortably. About twelve months previous to the date of my first visit, while lifting a wash-tub something "slipped back into her belly," and at the same time the abdomen became somewhat smaller. This was in all probability caused by the large fibroid uterus, which had been resting on the pubes, being suddenly dislodged. She now began to suffer acutely from pressure symptoms. The bladder and rectum prolapsed, and were for the most of the time between her thighs. She had difficult and scanty micturition, constipation was constant. Finally, the urine became loaded with pus; her abdomen became enormously distended with ascites, and she suffered constant pain, besides losing large quantities of blood. At the time of my taking charge of the case she could be out of bed only about two hours a day, on account of the great swelling of her legs and feet. She had been attended by a number of different physicians, and had been repeatedly tapped, the last tapping having been done on the Saturday previous to my seeing her. After each of these operations she was confined to bed for several days with an acute pain in the lower part of the abdomen, and she was now suffering from one of these attacks of peritonitis—so much so that I could only with difficulty manipulate her abdomen.

The diagnosis was extremely simple, and she readily consented to an operation, with the full understanding that the chances of recovery were strongly against her. On the following Saturday, just one week from her last tapping, I opened her abdomen, and removed a fibroid uterus, weighing five or six pounds. At the time of the operation her belly was so distended with fluid that her breathing was badly interferred with: over three gallons of fluid were removed. The operation was performed by the extra-peritoneal method. I was able to place the *serre-nœud* below, and including, as I then thought, both ovaries, and thus obviated the separate removal of these organs; this, however, finally proved to be a fatal mistake. In cutting away the tumor it be-

came necessary to leave part of the right ovary on the stump, in order that the button might be large enough to prevent the *serre-nœud* from slipping. The peritoneum was the thickest I have ever seen, being fully half as thick as one's finger. The patient recovered promptly from the anæsthetic, and much to my surprise went on slowly and without complication to recovery. For the first ten days I removed daily from the drainage-tube over a quart of straw-colored, syrupy fluid, and I was at one time afraid that the peritoneum would never stop secreting it. On the eighth day the stitches, fourteen in number, were removed and union found to be perfect, with no stitch-hole abscesses. On the eleventh day the discharge from the drainage-tube stopped abruptly, after a dose of salines, and never again reappeared. The tube was removed four days later. On the tenth day, while tightening up the *serre-nœud*, it broke and I was never able to tighten it afterwards. In consequence of this accident the stump was slow in coming away, and finally, after waiting a full month, and slight septic symptoms having set in, I removed the pus and cut away the decaying tissue as far as I could, and allowed the rest to retract. Within a few more days I had succeeded in getting away in small pieces the little tissue which was left.

At the end of six weeks she was out of bed and again at her work, in better health than she had enjoyed for years. The urine gradually cleared up and became normal. She had no more trouble from her prolapsed bladder and rectum; they disappeared entirely within the vagina. The depression left by the retracted stump never entirely closed, but continued to discharge from a pin-hole point, about one drop of pus daily.

Within a few weeks a ventral hernia began to show itself at the site of the drainage-tube, and gradually extended downward towards the pedicle, until finally it became as large as a big orange. This became more and more troublesome, and she complained of a dull pain at the lower part of the hernia. She being a poor woman, forced to work, and not capable of or having time to take the best care of herself, I advised her to go to bed again and have the hernia closed.

This she did on the 17th of last month. I opened the peritoneal cavity at the upper border of the hernia and slit up the tissues to the full extent of the rupture. Quite a large amount, probably a pint, of clear, straw-colored fluid gushed out. Passing my finger into the pelvis to investigate the cause of this, I was surprised to find it filled up with a cyst, having for its attachment the old uterine pedicle, which was itself thin and elongated. The pedicle of this new growth was very short and broad. After securing it with a double ligature, it was removed, and found to be a multilocular ovarian cyst about the size of a base ball. The omentum had been slightly wounded on entering the cavity, and as it bled freely a ligature was thrown around it, and a small piece removed. Everything being now cleaned up, a large flat sponge was placed over the intestines, and I proceeded to close the incision. The muscles and fascias were dissected out on both sides and united with a continuous silk suture. The wound was then closed by seven sutures introduced through the entire thickness of the abdominal wall. There was no drainage used, which was extremely unfortunate, for a drainage-tube would have saved her life. Recovery from the anæsthetic was prompt, and she seemed unusually comfortable. On the second day she complained of pain in the left chest, which for the next few days increased. This pain was apparently pleuritis, although I could discover no physical signs. She had a slight hacking cough, and about the fourth day began to spit up quite a good deal of dark colored sputa. For the first week she was extremely restless, and said she did not feel nearly as good as after the first operation. The temperature remained slightly over 100°, and the pulse about 90. On the seventh day the stitches were removed, and a drop of pus followed each of two of them; there was never any discharge from these points afterwards. This pus apparently explained her discomfort, lack of appetite, etc., but instead of improving, she grew slightly worse. From this time until the second of this month her temperature and pulse varied—on two occasions I found the temperature as high as 102°.5, but was never able afterwards to find it more than 101°.5. She complained, however, that her hottest time was towards morning, and that she sweated freely and could not sleep. Her tongue was of a nasty red color, irregularly covered with a thick white coat and pitted. By repeated examinations I could detect nothing wrong, and yet her whole condition seemed to me to be extremely suggestive of sepsis. On the seventh of the month I asked a friend to see the case with me, and advise as to the advisability of reopening her abdomen. Our decision was to wait and observe, and the old adage, "that he who

hesitates is lost," was once more exemplified. From now on I was led hither and thither by the symptoms; sometimes she was apparently much better, pulse and temperature would improve, and at one time the tongue was almost cleared, and the mouth was not so sore. About this time I noticed a distension of the abdomen, more on the left side, with a region of dulness irregularly extending from the spleen to the pubes. By change of position there was no change in the line of dulness. This led me to think that there had been an acute attack of peritonitis, with effusion, and that soon all would be well.

On the 8th of April about an ounce of pus was discharged from the site of the old pedicle, and after putting in a small rubber drainage-tube, the cavity was kept well washed out. With this cue to the probable trouble, I again lost my opportunity of operating. The symptoms all improved so much and she progressed so well for a few days that I was further seduced into the miserable policy of waiting. The pulse became 100 and the temperature 100°.5, and then things came to a standstill. I now went out of town for three days, determined to operate on my return if there was no more improvement. On my return, I found that there had been another discharge of pus, and that she was very much better. This led me into still more waiting, but without any further improvement.

Looking back over the past month, I could see a decided and alarming loss, which had been pretty constant in spite of the repeated changes for the better which had taken place in that time. On the 18th of April, about one month from the second operation, I undertook a third and last. The incision was made through the old wound. Here the tissues were an inch thick; hard and gristly. The hernia had been most effectually closed and the ends of the old suture could be plainly seen. Hemorrhage could only be controlled by sponge-pressure. On opening the peritoneal cavity, the trouble was at once apparent. A quart of foul fœtid pus was removed. The abscess cavity extended from the pelvis to the spleen. The intestines were crowded back and to the right and universally adherent, shutting off the abscess from the rest of the peritoneal cavity. Everything was covered with an apparent pyogenic membrane. The cavities were all thoroughly washed out and four rubber drainage-tubes put in, one extending to the spleen and one into the pelvis, the other two off sideways into deep pockets. The incision was then closed with four sutures. Recovery from the anæsthetic was prompt. Pulse was 130; temperature, 101°. But the pulse was 100 and the temperature 100° the next morning, and she was very comfortable. The tubes were washed out twice daily. For the first time for weeks she was able to retain much food. She was given every twenty-four hours twenty grains of quinine, f℥viij of whiskey, one pint of beef-tea and a pint and a half of milk, together with a couple of eggs. She retained most of this, taking part of it by the bowel and part by the mouth. In spite of all that could be done, the pulse and temperature slowly, but surely increased, until the thermometer registered 103° and the pulse counted 120. She sank slowly, and died the evening of the 24th, six days after the last operation.

No post-mortem was allowed, but on pretense of removing the drainage-tubes, the incision was enlarged and my hand introduced into the peritoneal cavity. Breaking up the adhesions surrounding the abscess cavity, I found there had been a slight general adhesion of all the intestines over the whole abdomen to everything. The liver and spleen substance were surprisingly firm. No more abscess cavities were found. The general appearance of the abscess walls was that of returning health: the pyogenic membrane had disappeared, and the peritoneum was beginning to look somewhat like itself. There was fairly good union in the incision, but it broke down readily under pressure.

In looking back over the management of this case, I recognize a number of fatal mistakes, and have learned some valuable lessons which I hope I may never have to relearn at the same cost. In the first place, all ovarian tissue should have been removed at the hysterectomy. However much I regret not having done this, there was at the time sufficient reason to justify leaving what little was left, especially as I thought the *serre nœud* was below it, and that it would all come away with the stump. I do not yet exactly see why it did not do so. The great error was in not being more careful in disinfecting the site of the old pedicle, which had never ceased to weep, before opening the peritoneal cavity a second time. The peritoneum undoubtedly became infected from this point during the necessary manipulations incident to the operation, and went on to a purulent peritonitis. Nature made a grand effort, even then, to save the patient, by throwing out adhesions as the inflammatory process advanced, and finally succeeded in saving half the cavity from involvement. After doing this, she gave all the indication

in her power as to what was the trouble, and by thrice discharging pus, apparently called loudly for assistance, which she failed to receive until it was too late.

Dr. H. A. Kelly said that he was sorry to say that he had required many lessons to teach him what Dr. Baldy hoped to have learned from this one experience. If anything went wrong which he could not attribute directly to the formation of stitch hole abscesses, and these did not cause any profound disturbance beyond a sudden rise of temperature, he did not hesitate to enter the peritoneum, with great care. On several occasions he had opened the peritoneal cavity five, six or seven days after operation, and in a case of day before yesterday, two weeks after the original operation. He usually does this without an anæsthetic or at most a few whiffs of chloroform, or cocaine locally. Cases requiring this have generally had a drainage-tube used and can be readily reopened in the track of the tube. The case of day before yesterday was a pyosalpinx, which had done well for ten days, and then the temperature and pulse began to rise. After giving a whiff of chloroform he introduced his little finger into the opening and penetrated to the floor of the pelvis when a collection of blood intermingled with pus made its escape. This did not seem sufficient to account for the symptoms, and by further bimanual examination he detected fluctuation on the right side, and with his finger broke through a thin wall and let out a teacupful of very fœtid pus. This was then washed out with his two-way catheter and a rubber drainage-tube inserted. Since then he has had his finger through that opening a number of times, for it has a great tendency to close. The case of Dr. Baldy's was instructive from the fact that it showed that there was a certain number of cases in which there is *dry peritonitis*, and the patients will sometimes die in spite of all treatment.

Dr. William Goodell said that he congratulated Dr. Baldy on the courage he had shown in the treatment of his case, and he thought he had nothing to regret. He always felt a good deal of reluctance in reopening the peritoneal cavity, but he had to resort to it occasionally. He did not think that the best method of curing the hernia had been employed. In his opinion the most satisfactory plan is, after dissecting out the sac and thinned-out tissues, to close the opening with three series of sutures. The first unites the peritoneum alone with a continuous gut suture. The second, also of gut, sews together the divided edges of the tendon. The third, of silk and interrupted, penetrates deeply through all the tissues but that of the peritoneum, and brings the edges of the skin and muscles together. The reason that we get hernia is that we fail to unite the tendon. To avoid the occurrence of hernia he had often thought it would be a better plan to cut through one of the recti muscles, instead of the linea alba, for then we have a broad raw surface. He occasionally resorted to this plan in oöphorectomy, but it has the objection of being accompanied with more hemorrhage. In large ovarian tumors the recti muscles were so widely separated that he was *per force* compelled to cut through their tendon, at the same time he admitted that he did not ordinarily unite these edges by a separate suture as is the custom of some excellent operators in this country. His reason is that this takes a good deal of time and it is always desirable to close the wound as soon as possible. But occasionally in cases of large ovarian tumors, he cuts away a long strip of the thinned tendon on either side of the wound so as to bring the muscles close together. In a certain number of cases, however, hernia will occur, and this was one grave objection to the use of the drainage-tube.

Dr. Parish asked if Dr. Baldy thought that the hernia was caused by the extra-peritoneal method of treating the stump?

Dr. Baldy said that the hernia was not due to the method of treating the stump. It began several inches above the stump and gradually extended towards it. He had, however, seen cases in which it occurred at the site of the stump, and he thought that this could not always be avoided on account of the large size of the pedicle and the subsequent contraction. He was glad to be able to criticise such a case in his own practice, as he could do so with more freedom than if it had happened to another. He thought it was his own fault that he had lost the patient. There were certainly enough symptoms to indicate the necessity for reopening the abdomen even a third or fourth time. The symptoms continuing after the first discharge of pus should have settled the question of reopening without any more delay. After the second discharge of pus he could not see why he had been so blind as to his duty. The patient would undoubtedly have recovered had the belly been opened early enough. Even as it was, after the long delay, she struggled along for about a week, but she was so thoroughly saturated with septic poison that she had not sufficient vitality left for the fight. He would not approve such a

policy of waiting in another, and could only excuse himself on the ground of lack of experience in such cases.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 3, 1888.

The President, A. JACOBI, M.D., in the chair.

DR. A. R. ROBINSON read a paper entitled,

Some Studies on the Sweat Glands.

The following were his conclusions: 1. Sweat glands commenced to form at the tenth week of fœtal life instead of in the fifth month, as stated by Kölliker.

2. At four and a half months the coil and lumen partly formed, instead of at the sixth or seventh month, as stated by writers generally.

3. Some ducts communicated with the free surface at four and a half months instead of at the seventh month.

4. The lumen is not formed by breaking down of epithelia, but by a process of secretion, the product collecting between the cells.

5. No cuticula, or lining membrane, existed in the secreting part of the gland, and this structure was not composed of endothelia. It was often present in the epidermis as far as the granular layer, and consisted of the footplate of the epithelia.

6. But one row of epithelium lined the excretory duct until the rete prolongation was reached.

7. The muscular layer is not derived from epithelium, and is situated between the membrana propria and the epithelium when forming a continuous layer, and when fibres are isolated a few might be in the capsule.

8. The sweat glands secrete not only fat, but also sweat. Proof of this was offered in a study of several pathological lesions.

9. Milaria rubra and milaria alba are forms of milaria crystalina or sudamina.

10. Lichen tropicus is a form of eczema situated around a sweat duct and associated with hyperidrosis.

11. Milaria crystalina (sudamina) is an exudative affection depending on a neuroparalytic congestion, and not a sweat gland disease.

12. There is an adenitis sudoripara resembling somewhat eczema or dysidrosis in clinical character.

13. There is a cystic disease of the sweat ducts with distinct clinical characters.

A description of the pathological findings in these several diseases was given, and went to show that the function of the sweat glands was not alone to secrete fat, as stated by Unna, but that they had the additional function of secreting sweat, the view which had generally been accepted.

DR. HEITZMAN did not regard the proof brought forward by Unna and others as to fat being secreted by the sweat glands convincing. He thought the muscular layer of the sweat glands lay external to the membrana propria.

Action on the proposition to extend the territorial area of membership of the Academy was postponed.

PERISCOPE.

Behaviour of the Blood in Ligatured Vessels.

Böttcher's researches on this subject, conducted according to the latest histological methods, are to be found in the *Arbeiten aus dem pathologischen Institut zu Königsberg.* They fully confirm the conclusions of Dr. Guterbock, also those of Professor Pick, of Prague, on the processes which occur in the (so-called) organization of thrombi. Böttcher finds that the blood contained in a portion of a vessel intercepted between two ligatures, applied under antiseptic precautions, does not coagulate. The changes which occur in the stagnated blood are as follows: 1. Arterial blood becomes venous in character by long standing. 2. The red corpuscles may remain perfectly intact, even after the circulation has been suspended for several weeks. 3. The leucocytes early undergo degeneration, even in a week, but their nuclei preserve their capacity for stains. 4. The blood-tablets may be found in well-preserved condition, even after several days' stagnation. Finally, enumeration of the various forms of leucocytes in rabbits' blood led to the conclusion that the "lymphocytes," that is, the small, uninucleated forms of leucocytes, poor in protoplasm, represent the majority of the leucocytes existing in the blood. This is contrary to the prevailing assumption on the subject, which puts these very forms in the minority. This is a point, as Guterbock remarks, of great importance in the study of the products of chronic inflammation, the leucocyte elements of which are mostly in the form of lymphocytes, as is well known, and this circumstance has been adduced as an argument against the hæmatogenous derivation.—*British Med. Journal,* January 21, 1888.

Early Rising and Longevity.

Professor Humphry's recent Collective Investigation Report on Aged Persons, contains some very positive evidence on a matter which has already engaged the attention of moralists as well as physicians. "The opportunity for nutrition to do its restorative work was in nearly all provided by the faculty of 'good sleeping,' to which was commonly added its appropriate attendant, the habit of 'early rising.'" Thus there is a relation between early rising and longevity. No doubt many people will hastily seize upon the sentence just quoted, and employ it in edifying lectures or essays for the perusal of youth, or embody it in popular medical works. Important qualifications follow in Dr. Humphry's report, but they are likely to be overlooked. Doubtless the habit of early rising is, in itself, healthy; most of all, it is a good sign of health when it evidently signifies rapid recovery from fatigue. Again, it usually denotes a strong will, the gift as a rule of a good physical constitution, or at least the safeguard of average bodily strength. Late risers are generally either invalids or persons of bad habits, idlers who are never free from other vices besides idleness. The nervous exhaustion which keeps a man wakeful thoughout the small hours produces sleep late in the morning. This exhaustion is invariably due to one of several life-shortening influences, especially anxiety or indiscretion in diet or drink. Early rising is thus rather one effect of certain favorable influences, another result of which is longevity, than a cause of longevity. To turn a weakly man out of bed every morning at 7 o'clock will not prolong his life. It will be noted that by "good sleeping" Professor Humphry signifies quick sleeping, "that is, the reparative work which has to be done in sleep is done briskly and well." Here, again, we have an effect of a cause; but preventing a weakly subject from sleeping more than four or five hours nightly would not cause him to live long, but would rather tend to shorten his life. Equally important are Professor Humphry's observations which show that by "early" he does not entirely mean the time by the clock. The word "has a relative significance with reference to the time of going to bed. A person who retires to rest four hours after midnight and gets up at 10 A.M. may be strictly regarded as an 'early riser.'" Thus, early rising is synonymous in long life histories, with short sleeping, which means rapid recovery from fatigue, a sign of bodily strength. These scientific facts in no wise contradict the alleged value of early rising as a practice to be cultivated by all persons in good health. It is excellent as moral discipline, and eminently healthy as a matter of fact. Most persons will eat three meals daily. When a man gets up late those meals will probably follow each other at too short intervals to be wholesome. When he is an early riser it will probably be otherwise. He can enjoy a good breakfast, and by the time for his lunch or mid-day dinner he will have an honest appetite again.—*British Medical Journal*, March 31, 1888.

Intra-Uterine Dentition.

In the *Boletin Clinico* of Lerida, Señor Lorens mentions a case of intra-uterine dentition. He recently attended a woman in humble circumstances in Barcelona during a premature confinement at six months. The child had already cut the four incisors and the two lower canines. Had the woman gone her full time the dentition would have probably been much further advanced.—*Lancet*, March 10, 1888.

Borofuchsin as a Stain for Tubercle Bacilli.

Professor Lubimoff describes in the *Meditsinkoe Obozrenie* a new stain for tubercle bacilli, which he calls borofuchsin. It consists of:

℞ Fuchsin.....7½ grs.
Boric acid.....7½ grs.
Absolute alcohol.....4 drachms.
Distilled water.....5 drachms.

When prepared in this way it has a slightly acid reaction; it is quite clear and not liable to spoil by being kept, and consequently it is always ready for use. The sputum is dried on a cover-glass and stained by being heated in contact with the borofuchsin for one or two minutes. The stain is then washed out by treatment with dilute sulphuric acid. The specimen is then washed with alcohol, and subsequently immersed for half a minute in a saturated alcoholic solution of methylene blue. After being washed in distilled water and dried, the examination of the specimen is made in oil of cedar or in a solution of Canada balsam. In exactly the same way sections of tuberculous organs may be stained after hardening in spirit, only in such cases the steps of the operation must be somewhat more prolonged. The main difference between this and other staining processes for Koch's bacilli is that, when borofuchsin is used, the process of washing it out with sulphuric acid is an almost instantaneous one. All other bacilli are, as when other stains are used, rendered colorless and invisible, the tubercle bacilli alone being seen.—*Lancet*, April 21, 1888.

Treatment of Empyema.

At the meeting of the Harveian Society of London, March 1, 1888, Mr. Mansell Moullin read a paper on the surgical treatment of empyema, based on an analysis of thirty-four cases. In sixteen of these a discharging thoracic sinus was already present. He pointed out that the primary cause of the collapse of the lung was the accumulation of fluid; but that the permanent cause of its non-expansion when the pressure was relieved was the alteration in the structure of the pleura and the lung itself, and that this alteration was the effect of the absorption from the irritating fluid in the cavity. When the air had already gained admission without drainage being perfect, so that the pus had decomposed, the thickening of the pleura was much greater and more obstinate than when the empyema had never been operated on at all. Everything pointed, except in children and tubercular cases, which were expressly excluded, to operation as early as possible. Primary resection of a rib was hardly ever required, unless the empyema was loculated; india-rubber tubes very soon wore the ribs away, so that there was little chance of their being nipped as the thorax collapsed. Two tubes must always be inserted, even if they were only a few inches apart; they might be in the same intercostal space, but there must be two for effective drainage. The most convenient situation was the one usually adopted, in the fifth or seventh interspace in the mid-axillary line. Washing out the cavity was quite unnecessary; if air was allowed to pass freely in and out there was no decomposition; the amount of pus discharged diminished almost to nothing, and the cavity rapidly closed in. In old cases the first thing was to establish free drainage by making a second opening; on five occasions it was necessary to trephine the ribs, as the wall of the chest had practically become a solid bony cuirass. In two cases some of the ribs had been resected; in one, two inches of four had been removed, in order to allow the thorax to collapse, but the patient, who was already suffering from amyloid disease, sank from exhaustion ten days after. In the other, portions of only two ribs were excised, as the sinus ran rather round the thorax, following the direction of those ribs, than upwards as in the former case. This was attended with considerable benefit. No trouble was experienced from the intercostal arteries on any occasion. The direction in which the sinuses run must in each case determine where the ribs should be cut, how many should be removed, and how much of each. Dr. Phillips criticised the view that an operation should be performed early. He had seen good results follow from aspiration. He also thought that two openings were not essential, and was prepared to show cases which had made a steady recovery after one. A hard-and-fast rule as to the best place for the opening could not be laid down.—*Brit. Med. Journal*, March 17, 1888.

Prognostic Significance of Blood Pressure in Acute Renal Disease.

In a paper read before the Medical Society of London, March 5, 1888, Dr. Broadbent said that though high arterial tension was present in almost every form of kidney disease, yet he had twice seen low tension when symptoms of renal cirrhosis were present. In acute renal dropsy, when the pulse beats were short and easily arrested, it indicated temporary dilatation and weakness of the left ventricle; from this the heart afterwards recovered. A continued defect of tension might be due to persistent cardiac weakness, and this latter was of unfavorable prognostic import; in other cases it indicated diminished peripheral resistance, and this also was of bad augury. He quoted the case of a carman of sober and steady habits, who was admitted into St. Mary's Hospital with acute renal dropsy of four days' duration. His mother had been of intemperate habits, and he had undergone privation two years previously, but no exciting cause of the attack could be found. He had swelling of the face, scrotum and extremities, a bad cough, and solid, albuminous urine, containing epithelium and casts. The temperature was subnormal; the pulse 64, short and weak. The first cardiac sound was short, the second weak, and there was extension downwards of dulness. Dr. Broadbent pointed out that the most certain cause of albuminuria was the languid movement of blood in the renal capillaries, and the indication here was to improve the circulation. Under a mixture of iron, sulphate of magnesia, nux vomica and digitalis, the dropsy diminished, the pulse became of better volume and not so compressible, and the albumin diminished to a little more than a trace. The patient was allowed to get up too early, and this brought about a temporary increase in the albuminuria. The imperfect development of blood pressure showed the nature of the patient's constitution, and might be made use of in prognosis. It indicated a long illness, and the necessity of the use of vascular stimulants.—*Lancet*, March 10, 1888.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., EDITOR.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,500 copies.

THE IMPROVEMENT OF MEDICAL EDUCATION.

At the last annual dinner of the Alumni of the Medical Department of the University of Pennsylvania, the Provost, Dr. Pepper, made a speech in which he described the advances made in the University during the last ten years toward a fuller and better system of medical education, and the hopes entertained by the Alumni and the Faculty that still further advances would be made in the near future. The success with which the University has maintained the system of an obligatory three years' graded course and longer annual terms has encouraged its friends to hope that very soon the period of study may be increased to four years. This hope is in the line of the wish of many advocates of higher medical education in the United States, as voiced by Dr. Garnett in his Presidential address at the last meeting of the American Medical Association, in Cincinnati. But we believe it is by no means certain that the object of this hope is likely to be reached very soon. The few institutions in this country which have so far adopted and adhered to the system of a three years' graded course have done so at considerable risk, and with a material diminution of the number of their students; and one of the most popular and widely known medical schools in America suffered so much in consequence of a step of this kind that it was compelled to go back almost immediately to the old two-term system. It cannot be said that the three years' system has yet established itself firmly, and we fear that an attempt to inaugurate a four years' system might not only fail of success, but actually imperil the stability of what seems now to be on the way to success.

At the dinner referred to, Dr. Alfred Stillé, Dr. Traill Green and Dr. William Hunt also spoke, and all of them urged the importance of making sure of a firm footing before attempting any further advance, and all seemed to feel that an attempt to establish very soon a curriculum covering four years of study within the walls of a medical school would be hazardous to the cause of higher education.

This feeling we know to be shared by many men who regard with satisfaction what has already been attained, and who hope to see still more accomplished. As we understand the matter, the things to be urged most strongly upon the medical schools of America just now are: first, the general exaction of an honest and adequate preliminary examination of those who propose to study medicine; and, second, the general adoption of a three years' course of intra-mural study. If these two things could be secured, the improvement in medical education would be enormous—far greater, we believe, than would be gained by the adoption of a four years' course by a few schools. For this reason, we believe that the friends of higher medical education would do well to devote their energies to persuading, or—if need be—compelling, all the medical colleges of the United States to adopt these measures, which a few have shown to be both desirable and feasible, rather than to widen the gap which even now separates the best schools from those which secure the largest number of students.

But there is another measure which, if it were adopted, would simplify very much the question we have been considering, and almost do away with the necessity for insisting on uniform conditions of study. This is the enforcement by law of a suitable examination by State or National Boards of candidates for a license to practice medicine. If this were secured, we believe all questions of medical education would soon be satisfactorily settled. Then the schools which furnished the best means of education would secure the largest number of students, and good education would be at a premium, instead of cheap and easy graduation.

For the present then, we believe the friends of higher medical education ought to labor most earnestly to have medical schools restricted to the work of educating their students, and to put the right to issue licenses in the hands of examiners who are not connected with the schools at all. This is the most urgent need just now, and to this we invite the thoughtful attention and active cooperation of our readers. Let them in their County and State Societies labor with earnestness and patience for the establishment of State Examining Boards, and we believe that before long the problem of medical education in the United States will be fully and satisfactorily solved.

ECTOCARDIA.

Among all the anomalies of development in human beings, none is more curious or more interesting than that in which the heart occupies an abnormal position or is devoid of its usual coverings. As long ago as 1826, Breschet published in the *Répertoire Général d'Anatomie et de Physiologie Pathologiques*, a paper on such anomalies, and a few years later Geoffroy Saint Hilaire included this subject in his admirable work on teratology. A number of cases have been reported in which the heart was in a situation more or less removed from the normal one, and exposed to view because of the lack of development of its coverings. In all of these cases, until very recently, death soon followed the birth of the child. But the *Bulletin Médical*, May 9, 1888, contains a paper read by Professor Lannelongue before the Académie de Médecine on May 7, reporting a case of this sort, in which he performed a plastic operation, and had the satisfaction of seeing his little patient recover and survive. This interesting case concerned a little girl six days old, when she was brought to Prof. Lannelongue, Feb. 15, 1888. She had a defect of the upper and middle part of the sternum and the overlying soft tissues, which left the ventricles of the heart exposed. The defect was about as large as a quarter dollar piece. At the time when she was first seen by Prof. Lannelongue there was a sort of membrane almost covering its heart, which presented a gangrenous appearance, and which soon sloughed away. After instituting some physiological investigations of the action of the heart, and waiting nine days to mature his opinion as to what should be done, Prof. Lannelongue closed the gap by a plastic operation, consisting in making two vertical incisions parallel to the long axis of the opening, and about half an inch from each edge, loosening the slips of skin, and sliding them toward the median line, until they could be united with three points of silk suture. Good, but not immediate, union followed, and in less than twenty days the whole surface was cicatrized and the opening closed.

The story of this case is of more than ordinary interest, because it furnishes a happy illustration of the result of a rare condition coming under the care of a man thoroughly competent to treat it. The history of the case does not indicate how it happened that the child was six days old before it was brought to the notice of a surgeon, and it is only just to our French brethren to suppose that the infant was born under the guidance of a midwife, and not of a physician. When the child was brought to Prof. Lannelongue, it was subjected to an operation so simple and so easy of performance as to reflect credit upon the judgment of the surgeon, but one which was hardly so remarkable as to justify the pride which it

seems to have excited in the hearts of his fellow Academicians.

In fact, while the operation was undoubtedly judicious and deserving of imitation, the interest of the case is largely that which attaches to its rare and curious nature, and—we venture to say—to the questions of embryology and physiology which it suggests. It would be useful to learn several things which are not stated in the report, for example: the appearance of the defect when the child was born, the character of the membrane which sloughed off, and the part borne by the process of ulceration in producing the complete defect. Finally, the exceedingly interesting report given by Prof. Lannelongue might be regarded as more complete if he had discussed the feasibility of some method of assisting nature to bring together the separated halves of the sternum.

These reflections suggest lines of thought which we cannot now follow out; but we commit them to our readers for their own pursuit. Certainly the case we are considering is rare and curious enough to engage more than passing attention.

THE AFTER-TREATMENT IN CATARACT OPERATIONS.

At the meeting of the American Medical Association, in Cincinnati, May 8, 1888, Dr. Julian J. Chisolm read before the Ophthalmic Section a paper describing the simple dressings used at the Presbyterian Eye and Ear Charity Hospital of Baltimore, after operating for cataract. From May 1, 1887, to May 1, 1888, Dr. Chisolm has treated seventy-four cases of simple senile cataracts. All of these were operated upon in the operating-room of the hospital, on a high, narrow table, and before large windows. In every case the biniodide of mercury solution (1 to 20,000) was freely used, both before and after the operation, as an antiseptic wash. After the operation for cataract extraction he has closed only the eye operated upon with a piece of white isinglass plaster, leaving the other eye open. None of the patients were put to bed. They were kept in a moderately lighted room, and were allowed to lie, sit or walk about as they wished. They dressed themselves, took their regular meals, received their friends daily, and had as little restraint imposed upon them as possible. The isinglass strap was inspected daily. It usually remained firmly adherent until the fourth or fifth day, when it was removed. As it was diaphanous, the condition of the eye-lids and eye secretions could be readily examined. Should the eye be painful at any time an atropia drop could be introduced by capillary action from the inner canthus. Salicylate of sodium was also given in twenty grain doses to sooth the eye and the patient. After four or five days the strap was removed and the eye left exposed. No smoked glasses were used, and none were needed. Dr. Chisolm has shown by his year's experience that if one eye is left open the other never becomes sensitive to light. When the strap is removed there is no weeping and injections, with photophobia—as is always seen when the patients' eyes have been dressed by bandages and they have been kept in dark rooms. The conclusion forced upon Dr. Chisolm is that most of the annoyances which follow upon cataract operations when the double bandage is used, do not depend upon the traumatism of the eye, so much as upon the too confining dressings. With seventy-four simple senile cataracts operated on during the year, not an eye has been lost. In every case a clear cornea has been preserved. In only two cases were the pupils closed from iritis, which will necessitate an iridectomy for the restoration of good sight. In no case was there suppuration. Dr. Chisolm's opinion is that when the operation of cataract extraction is smoothly done, and with every antiseptic precaution, it matters little what kind of after-treatment is adopted—good sight in every case is practically assured. If such results follow his method, then the annoying restraints heretofore practiced by all, and still used by many operators, are uncalled for.

During the discussion of the paper, many specialists present at the meeting endorsed Dr. Chisolm's conclusions, having adopted his method of light dressings with freedom of movements to the patient.

This method is one which seems, therefore, to be approved by experience, and to have decided advantages over those which were formerly considered necessary. To the patient it must be no small gain to be free from the disagreeable restraint of the bandage, and to be able to enjoy the pleasure of vision after operation, as well as to seem to himself and to his friends less an invalid than is possible with bandaged eyes and in a darkened room; while to the surgeon it must be a great satisfaction to know that this freedom from restraint is not gained at the cost of an increased risk, but rather contributes to a speedy and safe recovery.

WOUNDS OF THE PALMAR ARCH.

At a meeting of the *Société de Chirurgie*, of Paris, May 2, 1888, M. Bosquet reported a case in which the palm was severely cut with a fragment of a bottle, so that the flexors of the thumb and index were completely divided, and there was a profuse hemorrhage. After trying in vain, and for a long time, to ligate the divide vessels in the palm, M. Bosquet ligated the radial and ulnar arteries, presumably in the wrist. After this communication had been read, M. Championnière expressed the opinion that good compression would have controlled the hemorrhage and obviated the necessity for the operation of ligation in the wrist. To which M. Bosquet replied that he had feared to use prolonged compression on account of the pain it would cause.

We call attention to this occurrence because it indicates what we believe is a widespread error in regard to the treatment of wounds of the blood-vessels in the palm. Most works on surgery and most surgical teachers advise having recourse to ligation of the radial and ulnar arteries, when ligation at the original wound is very difficult, in a way which appears to do injustice to what can be accomplished by local compression; and M. Bosquet evidently ignores the value of compression, while M. Championnière appreciates it fully.

As a matter of fact, we believe that few wounds of the palm absolutely require ligation of the vessels in the wound, or anywhere else. And we think that the rule of practice ought to be: ligate in the wound, if this can be done without prolonged or laborious effort; and, if not: elevate the part and apply a compress which has been soaked in cold water, or some mild astringent, and then squeezed fairly dry, binding it on with moderate, but not excessive, firmness, and maintaining the hand in an elevated position. No one who has not tried it would believe how much can be accomplished by a rational use of elevation and moderate compression in the case of wounds of even quite large arteries; and we believe that distant ligation should never be appealed to until the method just described has been fairly tried. Certainly in wounds of the palm much trouble to the surgeon and some risk to the patient might be avoided if it were thoroughly appreciated.

CATHETERIZATION OF THE URETERS.

Catheterization of the ureters has lately been brought into prominence by several writers, and the subject is unquestionably one of great promise and importance. Its range of application too, is by no means so limited as would first appear. It can not only be used as a diagnostic measure, but it is also a most valuable aid in the treatment of urethritis, pyelitis, and sacculation of the pelvis of the kidneys and ureter. By means of this operation the urine from each kidney can be separately collected for examination, and the relative condition of the two kidneys can be much more accurately diagnosticated than has heretofore been possible. In cases of stone in the kidney or its pelvis, or other morbid condition, when nephrectomy or nephrotomy is indicated, the value of this method in deciding which kidney is diseased is apparent. We are not aware, however, that this has been applied in practice, except in the case of Iversen mentioned in our editorial in the REPORTER, May 19, 1888. By the use of the renal sound, stone in the ureter or renal pelvis can be diagnosticated. Thus far catheterization of the ureters has been principally employed in the treatment of catarrh or sacculation of the ureter and pelvis

of the kidney, by irrigation. Only women have been subjected to the operation. The catheter has been passed into the ureter, under the eye, through a vesico-vaginal fistula, or through the dilated urethra, employing the finger as a guide or free-hand, aided by a knowledge of the position of the urethral orifice, previously obtained by bi-manual examination. In some of the cases operated on, the fistula has been the result of traumatism, in others, it was made intentionally to insure drainage, and to facilitate catheterization. In the male, preliminary or supra-pubic cystotomy, would be necessary; but, since catarrh and dilatation of the ureter and pelvis of the kidney are usually secondary to cystitis, this is hardly a contraindication, especially when the very serious nature of the conditions is considered.

ACKNOWLEDGMENT.

We take pleasure in acknowledging our indebtedness to the reports published in the daily issue of the Cincinnati *Lancet-Clinic* for a part of our report of the proceedings of the last meeting of the American Medical Association. The work of our own special reporters was admirable, but by adding to it some extracts from the *Lancet-Clinic*, we have been enabled to present our readers with a report which was prompt, and, we believe, accurate, and which we trust will prove satisfactory to them.

—The *Ledger*, May 29, 1888, says that M. Oscar Schmidt, professor at the University of Gratz, in Styria, has discovered a method by which pieces of living sponge can be broken off and planted in a favorable spot. From very small cuttings of this kind Professor Schmidt has obtained large sponges in the course of three years, at a very small expense. One of his experiments showed that the cultivation of 4000 sponges had not cost more than 225 francs, including the interest for three years on the capital expended. The Austro-Hungarian Government has been so much struck with the importance of these experiments that it has officially authorized the protection of this new industry on the coast of Dalmatia.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

QUESTIONS AND ANSWERS ON THE ESSENTIALS OF PHYSIOLOGY. PREPARED ESPECIALLY FOR STUDENTS OF MEDICINE. By H. A. HARE, B.Sc., M.D., etc. With Illustrations. 8vo, pp. 170. Philadelphia: W. B. Saunders, 1888.

This book differs from most works intended for the use of medical students in that it imitates the style of the quiz class, being prepared in the form of questions and answers. The matter—as might be expected from the reputation of the author—is most excellent. The manner is dogmatic and well suited to the needs of the student preparing for examination. The author justifies his method by citing the existing state of medical education in this country, and some of his statements by the fact that physiology is a branch of science in which change is constantly occurring, so that a definite answer to certain questions is not unlikely to differ from the opinions of some authority. The needs of medical students, however, necessitate definite answers, and those given in this book represent very well the present state of knowledge in physiology.

A TREATISE ON FRACTURES AND DISLOCATIONS. VOL. II.—DISLOCATIONS. By LEWIS A. STIMSON, B.A., M.D., Professor of Clinical Surgery in the University of the City of New York, etc. Large 8vo, pp. 541, with 163 illustrations. Philadelphia: Lea Brothers & Co., 1888. Price: cloth, $3.00; leather, $4.00.

This is a very handsome and complete treatise on dislocations, and a fitting companion to the volume on fractures issued some time ago by the same author. Dr. Stimson has had a large and varied experience in the treatment of dislocations, and is thoroughly familiar with the opinions and methods of other surgeons in this country and in Europe. As a consequence, the volume before us will undoubtedly add to his reputation as a surgeon and as an author, and it can be recommended to our readers as a safe guide in practice. If we were to offer a criticism, it would be that, in the fulness of his descriptions, he has included some methods which are hardly other than surgical curiosities, and which are neither necessary to success nor indeed practicable for most surgeons. Still this adds to the completeness of the book, and does not detract from its merits.

MEMORANDA ON POISONS. By THOMAS HAWKES TANNER, M.D., F.L.S. Sixth American, from the last London Edition. Revised by Henry Leffmann, M.D. 32mo, pp. 177. Philadelphia: P. Blakiston, Son & Co. 1888. Price, 75 cents.

This admirable little book has been so long and so favorably known to the profession that it is not necessary to speak particularly of its merits. But to those who are not already familiar with it, it may be worth while to say that it is a compact and handy manual of the treatment of poisoning, arranged in such a way as to be a ready reference book for emergencies of this sort. It is a good book for students of medicine to carry in their pockets, and not a bad one for any practitioner.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—The prospectus of the *Texas Health Journal*, just received, announces that it is to be published as a monthly magazine, each number to contain thirty-two pages of reading matter devoted to the education of the people of that vast State in matters of sanitation, preventive medicine and dietetics. The editor is Dr. J. R. Briggs, and the place of publication, Dallas, Texas. The subscription price is to be $2.00 a year. The object of this journal is one deserving of hearty commendation, and it has our best wishes for its success.

—The publication of a new journal, entitled *Revue sur les Malaaies du Système Nerveux*, under the direction of Professor Charcot and M. Paul Richer, is announced. It will contain clinical observations and a descriptive account of the diseases of the nervous system observed at the Salpêtrière, in Paris.

Correspondence.

Appendix Vermiformis.

Editor Med. and Surg. Reporter:

Sir:—I notice in the Reporter, May 12, 1888, page 587, that Dr. Gaston says that the appendix vermiformis is not found in the lower animals, with the exception of some of the monkey tribe. In this he is certainly mistaken. It is present in the horse, sheep, chicken, and I think in the hog. I lost a valuable horse from strangulation of the small intestines, caused by the far extremity of the appendix adhering to the colon, forming a loop in which the constriction took place. I have always understood that condoms were made from the blind gut of the sheep. And as to the appendix in the chicken, I am very sure of that, having used them frequently in making a sac of thin peritoneal coating to be used in plugging the nose to stop hemorrhage.

Yours truly, A. Ady.

Muscatine, Iowa, May 17, 1888.

Formula for Paraldehyde.

Editor Med. and Surg. Reporter:

Sir:—I have occasionally desired a hypnotic for cases in which it was not advisable to administer any preparations of opium nor chloral hydrate. Paraldehyde appeared to act favorably in nervous irritability, or even cerebral exhaustion, as well as hyperæmia and insomnia, especially the latter; but it is a substance quite unpleasant to swallow. As the result of several experiments, I offer the following as forming a clear solution, which can be administered alone or mixed with water, without change:

℞	Paraldehyde	2 fl. drachms
	Glycerine	4 fl. drachms
	Simple syrup	8 fl. drachms
	Sweet spirits of nitre	10 fl. drachms

Oil of sweet orange (or oil of anise) twenty drops to flavor. Mix and unite by agitation. Dose.—One to four fluid drachms every hour, or two to four hours.

After standing a short time it loses some opacity and becomes clear. A few drops of tincture of cochineal is advisable to color. Alcohol may be substituted for the spirits of nitre, but in cases, requiring a rather large dose, might not be advisable. If any one can furnish a formula superior to the foregoing it would be a favor to do so.

Allen A. Rawson, M.D.

Corning, Iowa, May 10, 1888.

"Wasted Sunbeams—Unused House-tops."

Editor Med. and Surg. Reporter:

Sir:—I thank you for your editorial notice of a recent article of mine under the above heading—believing it to be a subject worthy of wide consideration.

I made two special points. First, a rearrangement of the upper floors of dwellings, so that "solaria" might be afforded for use in winter by children, invalids and others in the colder months. Second, a utilization of roofs as "home parks" in our cities. Allusion was made to ancient usages in these respects, with the suggestion that architects and sanitary science adapt such usages to modern homes and present civilization. The paper was suggestive; and though having well-defined designs of construction in my mind, left details for architects to define, as being best adapted to varieties of dwellings. Having consulted civil authority and the highest architectural and sanitary experts in regard to the feasibility of my suggestions, I can speak most cordially on the subject.

A recent writer in one of our great dailies, speaking from a practical knowledge of the subject, said: "The Board of Health, if necessary, could as readily regulate this matter of 'home parks' as it can other matters relating to the public health." * * * "Architecture and sanitary science are fully equipped to undertake the grand hygienic innovation proposed. Dr. Smith's suggestions are perfectly practicable, and if adopted, would add to the health, happiness and longevity of the people."

I thank you again for commending the ideas to the attention of your readers, "in the

hope that some of them may be able to suggest a plan by which they can be carried out."

Yours truly,

GOUVERNEUR M. SMITH.

14 East 17th St., New York City,
May 21, 1888.

Prescription for Headache.

EDITOR MED. AND SURG. REPORTER:

Sir:—I have tested the efficacy of the following prescription in no less than twenty cases, and find it by far the most valuable "headache cure" that it has ever been my good fortune *to try*, or to have seen recommended:

℞ Antipyrin.....gr. xv
Potassium bromide.....gr. xv
Tr. digitalis.....gtt. vij
Aquæ q. s. ad.....℥ ss
Mix. Sig.—Take at once. (For adults.)

The above is especially indicated in headaches of fevers, accompanied as they are, for the most part, by nervous phenomena, cerebral congestion, and a full bounding pulse. Also in the condition designated as "migraine," and in headaches of hysterical women.

In like conditions I have exhibited atifebrin, sometimes with success; less marked, however, than with antipyrin. Generally speaking, antifebrin seems to have a happier effect when the headache is occipital, and the heart's action rather weak.

In comparing the two, omitting, however, their relative sedative influence upon nerve tissue, the greatest advantage possessed by antipyrin over antifebrin is its *solubility;* which makes it of infinite value in malarial hyperpyrexia, accompanied by either coma or irritable stomach, or both, in which cases it may be administered hypodermatically.

Yours truly,

J. T. BRINGIER, M.D.

Burnside, La.,

Electrical Treatment of Pruritus Ani.

EDITOR MED. AND SURG. REPORTER:

Sir:—Dr. Stanbury Sutton is, in my view, correct in his estimate of the neurotic origin of pruritus ani and its treatment. Galvanism and Faradism will cure it, especially if combined with sodium bromide in large doses, hypophosphites, arsenic and regular laxatives.

Static electricity is better than Faradic, and easier and cleaner in application. This trouble, and eczema, so often occur incidentally in neurological practice, and these patients sometimes come to us for relief after the dermatologist has failed, so that a neurologist must of necessity get considerable experience in its management. There is a special form of hyperæsthesia in pruritus and a vasomotor paresis which under static electricity disappear as if by magic. I have seen the reddened and irritated skin about the coccyx and perinæum in the affection become promptly blanched by one seance, and the patient go out of the office completely comfortable for hours after one treatment. This must be followed by nightly doses of from forty to sixty grains of bromide of sodium combined, etc., as above indicated and often repeated to secure relief.

Yours truly, C. H. HUGHES.

St. Louis, Mo.,
May 7, 1888.

NOTES AND COMMENTS.

Battey vs. Tait.

One of the most exciting scenes which occurred at the late meeting of the American Medical Association at Cincinnati, was the speech of Dr. Robert Battey, of Rome, Ga., in which he discussed the question of priority in the Battey (or so-called Tait) operation. He completely captivated the section and was greeted with cheer after cheer. Those who know Tait's arrogance and self-conceit enjoyed the speech exceedingly, and to one who had heard Tait stand up in the British Medical Association at Dublin, and call American medical men "tramp doctors," it was a treat ever to be remembered. There are about this country certain young gynecologists who have gone to Tait, paid their twenty guineas for a month's assistanceship, and must continually talk about their teacher.

In discussing the paper which brought the subject up, Dr. Battey said: The author seems to know nothing about American work, in his use of the term Tait's operation. Tait cares nothing about the change of life; he operates for pain, not disease. The author argues this change of life very strongly. There was a humble American surgeon, who before this time, away back in 1872, suggested this operation and described it; years before Tait was heard to speak on the subject. The author of the paper speaks of Tait's struggles in introducing this operation. The older members of the profession will remember the struggles of the operation in the Georgia State Medical Society, The American Medical Association, and the American Gynecological Association. This was going on for years,

and Tait said nothing until May, 1879. Are we to accept the simple say-so of Tait that he thought of this operation and said so to Dr. Chadwick of Boston? Dr. Chadwick does not remember it; he may have said it, but he cannot certify that he did. Why should Mr. Tait come in at the end of the fox-chase and claim the tail of the fox? I have sat too modestly in my chair and allowed Mr. Tait to talk about "his operation." I despise this little quibbling fight, but when a member of my profession in my own national association talks so much about "Tait's operation," it is too much. Mr. Tait has recently shown so much modesty in saying that possibly it might have been thought of before, that you would not recognize that it was Mr. Tait. [Applause.] I forbear to reveal the secrets of Mr. Lawson Tait's hospitality to me in 1881, but he may provoke me to do so. [Hear! hear!] A little latter while enjoying the hospitality of Dr. Mathews Duncan, that straightforward specimen of a Scotchman, he said to me that he had hoped not to be called upon to invoke the aid of this operation, but he had. What Dr. Duncan said of Mr. Lawson Tait, deponent saith not. [Applause.] Mr. Tait found it necessary to resurrect a patient at the Congress of 1881, who was recorded dead years before in his own hand-writing. When asked how about this, he said: "Only a little clerical error." May God forgive Mr. Lawson Tait and prevent me from falling into his ways. I had to go over and pitch the battle in the British Medical Association under the nose of Mr. Tait. He referred to Tait's paper—"Normal Ovariotomy"—in the *British Medical Journal* in May, 1879. The essence of my operation is the change of life; Mr. Tait does not operate for this, and here is the dividing line. Hegar's operation is the Battey operation; he claims nothing else. It is only his friends who call it the Hegar operation.

The 0.25 Dioptric Cylinder the most Valuable Lens in the Trial Case.

Dr. Julian J. Chisolm read a very practical paper on the above subject before the Ophthalmological Section of the American Medical Association at its recent meeting in Cincinnati. He quoted text-books to show that very few writers on refractive errors were disposed to recognize less than a 0.5 cylinder for the relief of eye pains, and that V = $\frac{20}{20}$ was considered incompatible with astigmatic errors. From his very large experience over many years, he is able to formulate the statement that painful eyes, although they possess V = $\frac{20}{20}$ can have low degrees of astigmatism, and that such is a common fault in the over-worked, painful eyes of students. During the last year he had prescribed glasses for 986 astigmatic eyes, 546 of which exhibited a fault of only 0.25 of a diopter, and yet this small degree of error would not permit these irritable, painful eyes to be used. The correction of the fault restored at once comfortable vision. The use of a 0.25 D. cylinder by these eyes made the difference between not being able to read at all, and reading for hours at a time. Many ophthalmic surgeons both in their practice and their writings do not correct less than a 0.5 diopter astigmatic fault. In a great many of these cases the eyes continue to pain on use because of an over-correction. When glasses of only half this strength are used comfort is at once re-established. In over-worked eyes of the young great irritation and reflex annoyances develop from small degrees of irregular vision. Headaches of daily occurrence, which are attributed by one physician to gastric disturbance, by another to hepatic or renal or uterine troubles, by a third to nervousness, or to spinal irritation, and which in their continuance for months have resisted the skilled treatment of physician and gynecologist, have yielded promptly and perfectly to the continued use of weak cylinder glasses. Dr. Chisolm says in his paper that the reason why specialists do not find these low degrees of astigmatism is that with their preconceived views of its non-existence they do not look for it. The result is that many patients who seek their advice with painful eyes go away unrelieved. As he is aware of its importance and of the great annoyance which a 0.25 D. astigmatism occasions, he is always on the lookout for it, and frequently finds it to the very great relief of his patients. He prescribes more 0.25 D. cylinder lenses than any other; as very decided benefit comes from their use, he is forced to believe that this, the weakest of all the cylinders of the trial case, is in practice the most valuable.

Anti-Vaccinators.

It is stated that the partisans of the medical doctrines opposed to vaccination are organizing a Congress to be held in Paris in September next. The aim of the anti-vaccinators is to show that vaccinal inoculation is of no effect in preventing small-pox in spite of what has been proved by statistics; that the improvement in public health is the sole cause of the diminution of epidemics, and they point out that the Jennerian lymph is only a syphilitic virus more or less pronounced.

Rectal Insufflation of Hydrogen Gas in the Diagnosis of Penetrating Wounds of the Abdomen.

In concluding his paper on this subject, at the the last meeting of the American Medical Association, Dr. Senn expressed himself as follows: After a careful study of the subject of rectal insufflation of hydrogen gas in its various aspects, I do not hesitate to recommend its adoption in practice as an infallible diagnostic test in demonstrating the existence of a wound of the gastro-intestinal canal in penetrating wounds of the abdomer, without resorting to an exploratory laparotomy. In conclusion, I beg leave to submit for your discussion the following propositions:

1. The entire alimentary canal is permeable to rectal insufflation of air or gas.

2. Inflation of the entire alimentary canal from above downwards through a stomach-tube seldom succeeds, and should therefore only be resorted to in demonstrating the presence of a perforation or wound of the stomach, and for locating other lesions in the organ or its immediate vicinity.

3. The ileo-cæcal valve is rendered incompetent and permeable by rectal insufflation of air or gas under a pressure varying from one-fourth of a pound to two pounds.

4. Air or gas can be forced through the whole alimentary canal from anus to mouth under a pressure varying from one-third of a pound to two pounds and a half.

5. Rectal insufflation of air or gas to be both safe and effective must be done very slowly and continuously.

6. The safest and most effective rectal insufflator is a rubber balloon, large enough to hold 16 litres (quarts) of air or gas.

7. Hydrogen gas should be preferred to atmospheric air or other gases for purposes of inflation in all cases in which this procedure is indicated.

8. The resisting power of the intestinal wall is nearly the same throughout the entire length of the canal, and in a normal condition yields to diastaltic force of from eight to twelve pounds of pressure. When rupture takes place it either occurs as a longitudinal laceration of the peritoneum on the convex surface of the bowel, or as multiple ruptures from within outwards at the mesenteric attachment. The former result follows rapid and the latter slow inflation.

9. Hydrogen gas is devoid of toxic properties, non-irritating when brought in contact with living tissues, and is rapidly absorbed from the connective tissue spaces and all of the large serous cavities.

10. The escape of air or gas through the ileo-cæcal valve from below upwards is always attended by a blowing or gurgling sound, heard most distinctly over the ileo-cæcal region and by a sudden diminution of pressure.

11. The incompetency of the ileo-cæcal valve is caused by a lateral and longitudinal distension of the cæcum, which mechanically separates the margins of the valve.

12. In gun-shot or punctured wounds of the gastro-intestinal canal insufflation of hydrogen gas enables the surgeon to demonstrate positively the existence of the visceral injury without incurring the risks and medico-legal responsibilities incident to an exploratory laparotomy.

Ether Drinking in Ireland

In some places in the north of Ireland ether is largely used as a substitute for whiskey, one reason being its cheapness, inasmuch as a person can obtain for a penny sufficient ether to make him drunk. The subject of ether drinking was recently brought before the General Synod of the Irish Church. A clergyman proposed that a petition be presented to Parliament praying for the suppression of the sale of ether as an intoxicant in certain districts; but as it was pointed out that ether was sold for other purposes than as an intoxicant, he substituted the word "regulation" for "suppression," and the motion as amended was adopted. There is a special kind of ether sold prepared for drinking purposes, and although the Excise authorities have been applied to, they have refused to control its sale.—*Lancet*, April 21, 1888.

Peculiarity of American Eyes.

The efforts of the War Department to secure a field glass of greater power than the one they now use, has disclosed the fact that the eyes of the average American are closer together than those of men in foreign countries. The double glass, known as the field glass, now used, is weaker than that used in the armies of Europe. The only glass they can get of sufficient power is a single spy-glass, which is defective, in that it does not take in a broad enough field. This is a very serious defect in the equipment of the American army, but there seems to be no immediate prospect of its correction, because our eyes are too close together. Some of the colored troops may be able to use a different glass, but the white soldier cannot overcome this national peculiarity.

Alcohol.

Prof. Atwater says in the *Century:* Among the curious side issues of the current temperance discussion is the question whether alcohol is a natural product. This is, I believe, vigorously denied in some quarters. Alcohol, like bread, is manufactured artificially from a natural product. In each case fermentation, a natural process, is made use of. But while bread is known only as a product of manufacture, alcohol appears to be very widely distributed in nature, though in extremely minute quantities. Nor is this at all surprising. If grapes or apples, or their juice, be exposed to the air, fermentation sets in and the sugar and other carbohydrates are changed into alcohol. The ferments which cause the change are afloat in the air all about, and might not unnaturally attack similar compounds in other vegetable substances. Prof. Muntz, of the National Agronomic Institute, in Paris, has, by refined chemical tests, discovered evidences of alcohol in cultivated soils, in rain-water, in sea and river water, and in the atmosphere. He finds that vegetable molds may contain considerable quantities, and it appears probable that the alcohol "originates in the soil, from the fermentation of the organic matters in it, and is thence diffused as vapor in the atmosphere." Another side issue of our temperance discussion is the so-called "Bible wine" theory, which maintains that the wine used in Palestine in the time of Christ was not alcoholic. I have been unable to find evidence that the composition of the juice of the grape, the laws of fermentation, or the practice in the making and using of wine were different in that country at that time from those in other countries, or in that country at other times; and believe it safe to say that the theory that Bible wine was different from other wine, that it had not the alcohol which other wines contain, is without any basis to support it, in the opinion of the student of science.

Olive Oil for Gall Stones.

At the meeting of the Berlin Medical Society, April 18, 1888, S. Rosenberg exhibited 629 gall stones which were discharged from a patient after he had been treated with large doses of olive oil, as lately recommended in America. Doses of from three to six ounces were given. The gall bladder, which before the treatment was of the size of a small fist, has become so shrunken that it can now scarcely be felt, while the previous extreme distress of the patient has considerably diminished.—*Deutsche med. Wochenschrift*, April 26, 1888.

Distilled Water.

In his valuable "Manual," Adolph Vomacka says: "It is not every water that is fit for use in the preparation of a pure distilled water, and certain it is that the so-called "distilled water," which is merely a by-product of other processes (condensation water from steam engines, for instance), is not fit to use in most of our pharmaceutical laboratory work. We must have for these, and especially for hypodermic injection solutions, an absolutely pure distilled water. To obtain this Vomacka recommends following the directions of the Pharmacopœia of the Netherlands, which are in effect as follows: Add to the water which you intend to distil potassium permanganate, so long as the violet color produced by each dosage is evanescent. When this is no longer the case, add a solution of alum until a weak acid reaction is obtained. Let the water stand until a precipitate no longer falls. Draw off the limpid portion and distil, throwing away the first and last thirds which pass over; in other words, distil one-third, and throw away the distillate; distil, and reserve for use only one-half the remainder. This distillate may be relied on as chemically pure. *National Druggist*, April, 1888.

Antifebrine Mixture.

The *American Druggist*, April, 1888, gives the following:

Antifebrine	60 grains
Brandy	4 fl. drachms
Water	6 " "
Syrup	6 " "

Dissolve the antifebrine in the brandy, then add the other ingredients. Dose, a teaspoonful.

Milk Jelly.

As a variation in milk diet, the following is recommended by Prof. Liebreich:

Heat 1 quart of milk with 1 pound of sugar, and when the sugar is dissolved continue the heat, at a boiling temperature, for about ten minutes. Now cool it well, and then add, *slowly* stirring, a solution of 1 ounce of gelatin in a cupful of water. Next add the juice of 3 or 4 lemons and 3 wineglasses full of wine, brandy or other liquor. Set the glasses containing the mixture in a cold place, so that the contents may gelatinize. It is necessary to have the milk quite cold before the other ingredients are added, as it would otherwise curdle.—*American Druggist*, April, 1888.

Eye Inflammation dependent upon Lesions of Dental Branches of the Fifth Nerve.

In the *N. Y. Medical Journal*, April 14, 1888, Dr. F. W. Marlow reports three cases illustrating the dependence of eye-inflammation upon irritative lesions of the dental branches of the fifth nerve. The following is a summary of his paper:

1. The inflammation was most marked at the margin of the cornea. 2. The conjunctival affection was limited to congestion and slight swelling, there being no discharge of matter. It would thus seem probable that the conjunctival symptoms were simply secondary to the corneal. 3. The corneal affection was quite superficial, but extended over a considerable area. In the first case it much resembled that seen in inherited syphilis. In the two last cases there was a tendency to loss of epithelium. Thus it differed from the ordinary phlyctenular type of keratitis, which tends to be more definitely localized in one or more spots, and to be accompanied by well-marked ulceration and the development of blood-vessels on the cornea.

4. In all the cases there were variations in the condition from time to time, the symptoms never entirely disappearing (with the exception of those of the left eye in one case) in spite of the long-continued use of the usual local and general treatment.

5. When the dental irritation was removed the eye-symptoms disappeared rapidly and completely in each case, and so far without relapse.

There can be little doubt, he says, that the removal of the dental irritation and the disappearance of the eye-symptoms stood to one another in the relation of cause and effect, and he thinks it may fairly be said that the dental irritation aggravated and prolonged the eye-inflammation, if it did not, as indeed seems very probable, constitute the original exciting cause of the trouble. If we admit, he concludes, that the condition of the teeth influenced the eye trouble in any way in these cases, it becomes evident that a dental lesion too slight, or at any rate not of a nature to call attention by symptoms to itself, may yet be sufficient to exert such an influence.

Ohio State Medical Society.

The forty-third annual meeting of this society will be held in Columbus, Ohio, June 13, 14 and 15, 1888. The sessions of the society will be held in Wirthwein Hall, the first session beginning at 2 P.M., Wednesday, June 13. A very full and interesting series of papers is on the programme.

NEWS.

—Dr. Frank P. Foster, editor of the *New York Medical Journal*, is said to be lying ill with perityphlitis.

—A Chinese surgeon, named Leon Jack, has recently arrived in New York and established himself in practice.

—The Medical Examining Board of Virginia has examined thirty-three graduates in medicine for license to practice medicine in Virginia. Twenty-six of the applicants passed, and seven were rejected.

—Dr. F. C. Shattuck has been appointed Jackson Professor of Clinical Medicine in Harvard University. Dr. Whittier, who has been Assistant Professor of Clinical Medicine for sixteen years, has resigned.

—Dr. William G. Goddard, who died in Boston, May 2 , was the oldest living graduate of Harvard College, the only survivor of his class, and the oldest graduate of the Medical School. He was born in 1796.

—Dr. Curschmann, Director of the Medical Department of the General Hospital, Hamburg, has been appointed to the Professorship of Clinical Medicine at Leipsic, made vacant by the death of Professor E. L. Wagner.

—A recent writer in the *British Medical Journal* declares that excessive tea drinking is the cause of early decay of the teeth, possibly through so altering the normal secretions of the mouth as to permit the development of acids and micro-organisms.

—Dr. William White, for many years the army apothecary at the office of the attending surgeon of the United States Army in Washington, D. C., resigned that office in May, on account of ill health. Dr. White has served twenty-seven years, under six different surgeons-general, and was the only man holding office as army apothecary. He was appointed from Pennsylvania.

—During the four weeks ending Tuesday, May 22, the following cases and deaths from infectious diseases were reported to the Sanitary Bureau of the Health Department of New York City: Typhus, 1 case; typhoid fever, 31 cases and 17 deaths; scarlet fever, 772 cases and 135 deaths; cerebro-spinal meningitis, 20 cases and 21 deaths; measles, 602 cases and 34 deaths; diphtheria, 734 cases and 213 deaths; small-pox, 66 cases and 24 deaths.

HUMOR.

A PHYSICIAN says: "If a child does not thrive on fresh milk, boil it." This is too severe. Why not spank it?—*Sinapore Review.*

A UNITED STATES SENATOR who has been called the silver-tongued orator, recently attacked a political opponent in such a caustic fashion that a correspondent of the *New York Evening Post* suggests that his title be changed to "nitrate-of-silver tongued."

AN EDITOR'S MINORITY.—Editor (to young man)—"Your article, I am sorry to say, is hardly up to our standard."

Young man—"Why, my mother thinks it's clever, my wife thinks it's clever, and I think it's clever—three to one, sir; the balance is in my favor."—*The Epoch.*

NOTHING SERIOUS.—Miss Clara (to Featherly, who is making an evening call)—"Poor little Bobby swallowed a penny to-day, and we've all been so much worried about it."

Featherly (somewhat at a loss for words of encouragement)—"Oh, I—er—wouldn't worry, Miss Clara; a penny is not much."—*Harper's Bazar.*

A MIND READER.—The waiter expostulates with a guest for summoning him by a snapping of the fingers, with the remark:

"Are you calling for the dog, sir?"

"Goodness!" exclaimed the guest, "are you a mind reader?"

"Why do you ask?" inquired the waiter.

"Why," returned the guest, "I was about to ask for the sausage."

A LITTLE BUFFALO GIRL was not feeling well, and her parents suggested that she might be about to have chicken-pox, then prevalent. She went to bed laughing at the idea, but early next morning went into her parents' room, looking very serious, and said: "Yes, it is chicken-pox, papa. I found a fedder in the bed."—*Christian Leader.*

A THREE-YEAR-OLD PHILADELPHIAN had heard her parents discuss hygiene until her infant mind was soaked with the subject. One day her dear old grandmother said—meaning to give Bessie a piece of cake—"Bessie, what do you always have after your bath?" The child regarded her grandmother for a moment with inquiring eyes, and then replied: "Reaction."—*Christian Intelligencer.*

IT SEEMS IT IS VERY IMPROPER to question a physician as to the special ailments of one of his patients. On the ordinary grounds of courtesy such a question is impolite, but one can imagine circumstances under which it is pardonable. Somebody who was not informed ventured to ask a Winchester doctor not long since what was the matter with a friend who was under his care. "Matter?" grunted the disciple of Æsculapius. "Matter? Why, she's sick."

LITTLE WILLIE HAD HAD THE SUBJECT of a new brother or sister mentioned to him as a probability in the near future. One morning the nurse called him and said: "Willie, here is a little sister the angels brought you last night." "Oh! let me see!" cried Willie in glee; "the angels never had any parasols, did they?" "Why, what a question. Why do you say so?" "'Cause they let her get sunburnt. She is right red. Take care, let me by, quick." "Where are you going?" "Going to tell mamma. She don't know yet."—*The Colonel.*

OBITUARIES.

EDWARD S. DUNSTER, M.D.

Dr. Edward S. Dunster, A.M., M.D., Professor of Obstetrics and Diseases of Women and Children and Clinical Gynæcology in the University of Michigan, died May 3, 1888, at Ann Arbor. Professor Dunster was a lineal descendant of Henry Dunster, the first President of Harvard, and was born at Springvale, Me., in 1834. He took the degree of M. A. at Harvard in 1856; M.D. at the University of the City of New York in 1859; was Demonstrator of Anatomy at Dartmouth College from 1859 to 1860; Surgeon in the United States army from 1861 to 1866; Professor of Obstetrics and Diseases of women in the University of Vermont from 1868 to 1874; editor of the New York *Medical Journal* 1866 to 1871. Since 1874 he had held a Professorship in the University of Michigan. He was also the author of several medical works.

CHAUNCEY L. MITCHELL, M.D.

Dr. C. L. Mitchell, an old and well-known physician of Brooklyn, died in that city May 8. He was born in New Canaan, Conn., November 10, 1813. After graduation from Union College, Schenectady, he studied in the Medical Department of the University of the City of New York, from which he was graduated in 1836. He was a member of the New York County Medical Society, the New York Academy of Medicine, the American Medical Association, and the Kings County Medical Society, of which he was thrice chosen President. He was consulting physician to the Long Island College Hospital, St. John's Hospital, and the Home for Aged and Infirm Men.

FOR SALE.

Two-wheeled Doctor's Gig, nearly as good as new. Original cost $450. Price, $100 cash.

Apply to Hilly's Stable,
20th St. above Chestnut, Phila.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session in addition to four Didactic lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars see annual announcements and catalogue, for which, address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

MAIL A POSTAL CARD

giving your name and address, to the publishers of the PITTSBURGH MEDICAL REVIEW and it will be sent to you for three months free of charge, and

At the expiration of this time the REVIEW will be discontinued, unless otherwise ordered.

Advertising agents, subscription solicitors and all travelling agents for reputable drug houses and publishing companies, who are free to solicit subscriptions, will do well to correspond with the

Clinical Lecture.

OSTITIS OF KNEE; TREATMENT OF ABSCESSES; KNOCK-KNEE; DISLOCATION OF BOTH TIBIÆ.

BY VIRGIL P. GIBNEY, M. D.,
PROFESSOR OF ORTHOPŒDIC SURGERY IN THE NEW YORK POLYCLINIC.

Treatment of Tubercular Ostitis of the Knee.

Gentlemen:—My remarks to-day will be divided into about three equal parts. I shall first speak of the treatment of chronic disease of the knee-joint, what is commonly called white swelling, and which of late years has come to be recognized as tubercular ostitis of the knee, whether it be of a deforming or non-deforming kind. As a rule, ostitis of the knee-joint, that is, inflammation of the bones entering into the formation of the joint, is attended with deformity. A deformity of the knee is very easily recognized, consisting usually of flexion which is frequently combined with subluxation and outward rotation. Fortunately, the most common deformity is flexion.

The mode of correcting flexion of the knee which I shall recommend to you as the best for adoption can be readily demonstrated, and its superiority be easily proven. I may say in this connection that the management of deformities at the knee in children, as practiced by surgeons in this city has varied very much, and the methods adopted have been complex. There have been innumerable splints invented for the correction of the deformity, but I have found that they are generally unsatisfactory. At least surgeons, other than the inventors of these apparatuses, and who are familiar with their use, tell me that such splints are commonly complicated and unsatisfactory; that they do not give the results which the inventors claim for them. I do not hesitate to say that the question of the proper treatment or correction of deformity of the knee in children has not yet been fully settled. The method which I am now employing I regard as the best one known to many of the profession, because of its simplicity and efficacy. There is nothing in the whole range of joint surgery which has pleased me more than this simple contrivance. Heretofore a knee-joint deformity has been a source of great trouble to me; I have taken hold of it with much misgiving. I have adopted several forms of splint for individual cases, but after trying them awhile I would discard them and try others. I would also give ether, divide the hamstrings, put the leg into good position, apply a plaster-of-Paris dressing; but you will find that this method to one who has many cases to treat proves unsatisfactory in the end. I still have half a dozen patients coming to this clinic who have undergone this method of treatment; they have been etherized on various occasions. The limb has been brought into quite, or nearly a straight line, and locked in a hard plaster-of-Paris cast. They have then been sent home with the leg in good position, but they would come back again with an excoriation which compelled me to leave the splint off for a time, a substitute being applied; but the next time they returned the deformity would be found to have recurred. I have gone through with that experience many times the past five years, and it now pleases me very much to be able to say to the parents of such children that there is a method whereby this deformity can be corrected with much certainty.

The method may be described as follows: Two fan-shaped pieces of tin or steel, each

applied to an iron bar, are connected at the smaller expansion by a joint. One fan-shaped piece fits the outer surface of the thigh, the other the outer surface of the leg, the joint being at the knee; a similar instrument being applied to the inner side. The whole is of very simple construction, and can be made by yourself or by any smith. The leg is then covered by a skin-fitting stocking or flannel bandage, some turns are made around the limb with the plaster-of-Paris bandage, then this instrument is applied and covered with the plaster-of-Paris. The lower part of the patella, bordering on the ligamentum patellæ, should be left exposed, not covered by the plaster. The bandage should be applied very thickly in the popliteal space. The limb should be put up in the position you find it, without any extension being made. While the cast on the leg is still damp, take your knife and make a transverse section of it down to the skin through the popliteal space. This completes the first dressing. The patient should now be allowed to go home, and the cast to become completely hardened before you do anything further. After twenty-four hours, and from day to day, if necessary, from week to week you can proceed to straighten the limb with manual force by degrees, maintaining what you gain at each visit by inserting a piece of cork between the divided portions of the plaster cast in the popliteal space. A piece of adhesive plaster passing over the cork to the cast on either side will retain it in position.

I have a patient now undergoing this form of treatment—a woman about twenty-five years of age, who has had deformity of the knee ten or fifteen years. The leg was fixed by fibrous ankylosis at an angle of 135°. She was walking with a decided limp, sometimes supporting the body with the hand on the thigh. When I saw her she was wearing a brace, which gave a slight amount of support, but it did nothing toward straightening the limb. I applied this splint five or six weeks ago. There was considerable tenderness when the first extension was made. I desisted for a week, let the joint alone, had her lie down a good part of the day, and kept the limb at rest. At the end of a week, I straightened the limb a little more. Although I have had to allow a week's interval each time, the limb is now straightened to an angle of 160°. Ordinarily in children the stretching and straightening process can be repeated each day, so that usually you can within a week overcome the deformity and produce very little pain.

Next you will want to know what to do with the limb after having corrected the deformity. Almost any person can correct the deformity, but very few know how to prevent it from relapsing. After straightening the knee completely, you should take off this splint and apply a solid plaster-of-Paris bandage with the limb in the best position which you are able to secure. You should get the limb entirely straightened before removing the first apparatus. After applying the solid plaster-of-Paris bandage you can use a splint known as Thomas's, invented by Hugh Owen Thomas, of Liverpool. It differs from others in that it does rely on adhesive plaster for extension and counter-extension. Most instruments for this purpose are attached to the thigh through adhesive plaster and by means of traction. It is claimed they extend the leg and keep the joint at rest. But a little thought will convince one of the insecurity of this method, for the muscles move upon the thigh, and the skin upon the muscles, so that an enormous amount of traction will have to be made upon the skin to protect the knee against traumatism. Thomas's splint relies for counter-traction upon a perineal ring. The perineal ring at the top and a ring at the bottom are connected by two iron bars, which taper from above, and extend three or four inches below the sole of the foot when the leg is straight. The difference in length between this instrument and the deformed limb is added to the shoe of the sound limb. The child then walks practically on a pair of stilts, but on the affected side the weight is thrown upon the stilt through the perineal ring, and the limb swings down between the two bars. If you do not wish to use plaster-of-Paris in keeping the knee straight, you can obtain this object by a roller bandage. This instrument gives rest to the knee and protects it against traumatism, and the weight of the limb swinging between the iron bars is sufficient to overcome the reflex spasm, which is an annoying symptom of the disease. You will find that under this treatment the infiltration about the joint will subside, that after awhile you will be able to move the patella over a greater area, and that if you attempt to move the limb you can obtain a small amount of motion. But it is best at first not to attempt passive motion. Leave that to nature and the child's volition, and you will sometimes see results which are marvellous. That is, in watching a knee of this kind pass through its different stages, with or without abscess, you will be surprised to see it come out straight, with a small range of motion, which

will increase as time goes on. Of course it is sometimes very embarrassing to a young woman to go on a crutch of this kind, but that does not militate against its usefulness and the necessity of employing it if you want good results.

The first instrument described to-day, employed in straightening the limb, I call Billroth's splint, for the reason that in Glasgow in the Summer of 1887, where I first saw the splint used, Dr. Cameron told me he had recently seen an assistant of Billroth, who said that at the clinic in Vienna they were in the habit of straightening knees by means of this appliance. Having never seen it employed elsewhere, Dr. Cameron and I called it Billroth's splint.

Its use is illustrated in the case of the patient before you, a little girl four and a half years of age, who, according to her mother's account, first complained of her knee about eight months ago. The mother knows of no special cause for the trouble, but thinks it may have been due to a blow with a slate. Noticing that the child walked lame, she inquired and learned that it complained of soreness in the knee. She first noticed contraction or deformity in the knee five weeks before coming to my clinic. About four weeks ago we applied the Billroth splint, and the limb, as you see, is now straight. We will leave the Billroth splint on the limb another week, when it will be removed and the Thomas splint substituted. The latter instrument will be worn at least eighteen months, as it is desirable during that length of time to relieve the joint of all jar and prevent recontraction. While wearing the Thomas splint she will run about and play as she may like.

To illustrate the inefficacy of some other methods of treatment, I present you a boy, seven years of age, a resident of New Jersey, who had been lame three years last January. He came here with a deformed knee, and he has deformity of the knee to-day. The popliteal space is covered with cicatrices left by abscesses, some of which have not yet closed. The limb is atrophied, and forms an angle at the knee of about 135°. The patient has been etherized a number of times and the limb stretched until it had become pretty straight, but something would then occur to interfere with the treatment and to conspire against his recovery. He has been wearing a Thomas splint. I shall now apply a Billroth splint, protecting as well as it may be done the sinuses in the popliteal space, and I doubt not that within ten days the limb will be made straight. I will give as much time as ten days, because there will probably be more pain than usual, necessitating a slower stretching process. I am asked whether I would apply the Billroth splint in a case in which there is free suppuration. I would, but I would leave an opening in the dressing through which I could secure free drainage, and I would leave the limb in a solid plaster-of-Paris dressing until the acute process had subsided, and then begin extension. You can, at whatever stage you begin the treatment, succeed in straightening the limb, except in bony ankylosis.

On Operative and Non-Operative Interference with Abscesses.

The little boy now before you, five years old, has been under treatment for hip-disease about a year and a half. He is now wearing a simple stem splint. The limbs are very nearly parallel; there is some atrophy, but there is very little deformity. Very little flexion is allowed, but the limb can be readily abducted.

A fact of some interest in the case is the presence on the outer aspect of the thigh of an open sinus which discharges pus. This was not present when the boy last visited our clinic. The mother says a "big lump" formed on the outer aspect of the thigh, which "bursted" and discharged "yellowish water." This is a typical instance of the way in which these abscesses sometimes come and go. Here it has not been interfered with at all; while the patient was playing in the street the abscess broke, and nothing was done except that the mother put a piece of cloth about the limb. But the boy shows no constitutional disturbance. On the other hand, there is another boy, of about the same age, and having a similar condition, who some days ago had an abscess on the thigh, which we opened under strict antiseptic precautions, thoroughly emptied the sac, washed it out with corrosive sublimate solution, 1–3000, applied iodoformized gauze and a solid plaster-of-Paris dressing. Yet the father has brought the boy back to-day because of constitutional disturbance. He has a pulse of 120 and a temperature of 101° F.

Orthopœdists often see cases like this, the first named. They put a splint on to protect the joint and keep the limb in good position; send the child out of doors to play; abscesses come and they pay no attention to them, but let them break when they will. The only inconvenience is that the child's clothing is soiled a little. The mother puts a "cloth about the sore," and the child continues running about on the splint. Its health

suffers very little. Finally the sac closes down and there remains only a small sinus or fistulous tract which may continue indefinitely. All the time the child's health continues and it seems to do remarkably well.

There are many cases giving such a history, and to surgeons who claim that wherever pus is found it should be evacuated at once, the orthopœdist replies that in these cases the pus does not cause any trouble whatever; that if the joint is protected, as a rule, good results will be obtained. But it is very difficult to convince anybody who holds the views surgeons generally do about the necessity of interfering promptly with everything surgical. But we can only let them go on believing as they will, while we go on getting good results by our method of treatment. In saying "we," I speak as an orthopœdic surgeon with a leaning toward meddlesome surgery when not against my strong convictions. I know that these abscesses will, if let alone, and the *hip is not protected,* do badly. They go on to produce septic poisoning and to cause irritation about the muscles; sometimes they produce a foul, disagreeable condition, and the child wastes, and dies from sheer exhaustion or amyloid degeneration. But it is an exception to find such a condition of things when you do all that may be done to protect the joint against reflex spasm, to prevent the bones from grating one against the other, to preserve the general health, yet leave abscesses to pursue their own course. Holding this view, I shall not touch the abscess in the boy presented, not even to wash it out. We will give him the benefit of a little wholesome neglect, and simply instruct the mother to grease the parts now and then with some vaseline, and to apply oakum to protect the clothing from the discharges.

A second abscess, small in size, is forming over the anterior superior spinous process of of the ilium, but in view of the fact that the other has done so well, and his general condition has not suffered from it, we will allow this one also to pursue its course, and not evacuate it in spite of the strong temptation to do so.

Congenital Knock-knee.

In this little girl we see what lately was an extreme case of congenital knock-knee, referred to me some weeks ago by Dr. Yale. There was lateral displacement of the patella with knock-knee, and there was also an extreme degree of valgus of both feet. The child had been wearing a knock-knee brace for about two years without any noticeable result. Dr. Yale agreed with me that the proper treatment was osteotomy. The usual supra-condyloid operation was undertaken first on the right limb. When I divided the femur, the patella slipped into place, but I thought there was going to be overlapping of the fragments. This, however, was avoided by traction; a bandage was put on, covered by a plaster-of-Paris dressing, and at the close of the operation the child was taken home in a carriage. No unfavorable symptoms followed, and six weeks later the operation was undertaken on the other limb. Following this operation, however, some swelling of the foot took place, and the patient was in much agony, so that it became necessary to remove the bandage. The bandage had been applied too tightly. She then went on without further symptoms. You now see that her limbs are about parallel; she has no knock-knee. She can bend her knee pretty well. There has been good union between the fragments. She wears a simple knock-knee spring at present to prevent any recurrence of the deformity. Before the operation the malleoli must have been separated a distance of a foot in the standing posture. The incision was made half an inch above the patella and half an inch in front of the tendon of the adductor muscle. Lay your finger across the leg at the upper border of the patella, and along its upper margin draw a line with a lead pencil. Then place your finger on the inner side of and parallel with the adductor tendon, draw a line along its upper margin, and at the point where these two lines intersect make the incision down upon the bone. Leave the scalpel in as a guide to the osteotome. Place a sandbag beneath the knee as a support when using the mallet. Having partially divided the bone you will fracture it by manual force. If you think it necessary you can afterward put in a suture, apply iodoformized gauze over the wound and dress with plaster-of-Paris.

I shall not allow this girl to stand on her limbs for some weeks, for she is frail, and we should run no risk of having the bones broken. Her limbs will be kept straight by this apparatus. The deformity of the foot, which is well marked on one side, will be corrected by a properly constructed shoe, throwing the weight of the body on the outside of the foot, and thus develop the arch.

The question is asked whether it is not better to operate on the outer side than on the inner side of the thigh. That subject has been much discussed, especially in England; and Macewen, of Glasgow, who

has operated thousands of times, gives preference to the operation on the inner side.

Congenital Forward Dislocation of the Upper Ends of Both Tibiæ.

This child, now five months old, was brought to the clinic when three weeks old, when we found extreme hyperextension of the leg, the articular surfaces of the tibia resting where the patella should rest, on the femur, and the articular end of the femur being felt distinctly in the popliteal space. I gave her a little chloroform, and it required about all my strength to place the limb in the normal position. But there are so many creases in the infantile thigh that I did not dare at that early period to put on a plaster splint. I therefore simply flexed the limb and let it return again to its former position. Dr. Ripley saw the child, and did the same thing under chloroform about a week later. Afterward I again reduced the luxation and applied a bandage, which, however, caused some excoriations. When the infant had attained the fourth month I applied a plaster splint, and the limbs are now in very good shape.

Toward the close of his clinic Dr. Gibney presented a number of patients, among others, a young woman who showed the benefits of systematic exercise in lateral curvature of the spine.

—A most heartrending story has been going the round of the German lay press. A goose was bitten by a mad-dog, and shortly afterwards it was killed and eaten by a peasant and his family, the family consisting, in addition to the man, of wife, son, daughter, and maid-servant. In due time symptoms of madness showed themselves in one member of the family after another. First of all the father was attacked, and died in the greatest agony; next followed the daughter; and after her the son was seized with the most frightful spasms, and all the other symptoms of canine madness; then came the wife and maid-servant. Naturally such a dreadful calamity caused the greatest excitement and the deepest commiseration in the whole of the surrounding district. Three doctors from Kolin and a professor from Prague were assiduous in their attentions, but all was in vain. So far the newspaper story. The actual facts (our German correspondent informs us) were these: A peasant's son died of Bright's disease as the post-mortem showed, and a daughter became insane and was removed to an asylum at Kolin. There was no mad-dog, no goose, and all the other members of the family continued in their usual health.—*Medical Press and Circular*, April 11, 1888.

Communications.

Report of Four Cases of Trephining the Skull.[1]

BY H. O. WALKER, M.D.,

PROFESSOR OF ORTHOPŒDIC SURGERY, GENITO-URINARY DISEASES, AND CLINICAL SURGERY IN THE DETROIT COLLEGE OF MEDICINE, DETROIT, MICHIGAN.

Trephining for Intra-cranial Hæmatoma, with Hemiplegia; Recovery.

Case I.—Joe S., Pole, aged 35 years, was brought to St. Mary's Hospital, February 11, 1887, by the patrol wagon, having been picked up the night previous by the police and put in the station, being registered as a common drunkard. I did not see him until the next day, when the house surgeon reported the case to me. Since his entrance to the hospital he had slept most of the time, and it was with some difficulty that he could be aroused. The only information that we could get from him was that he had pain in the left shoulder. We were completely in the dark as to his history. A careful examination of his entire body failed to give us any evidence of the slightest injury. There was paralysis, not complete, of the left arm and leg, with incontinence of urine, pulse 40, respiration 12, and temperature 98° in the axilla. The pupils responded to light. When aroused, he swallowed whatever liquid was given him. I directed full doses of bromide of potassium and a copious enema.

February 13. His condition remained unchanged; the bowels had not moved.

February 14. Condition the same, with the exception that the paralysis was becoming more complete and it was more difficult to rouse him. I ordered drop doses of ol. tiglii until an action of bowels occurred. Three drops were given without avail.

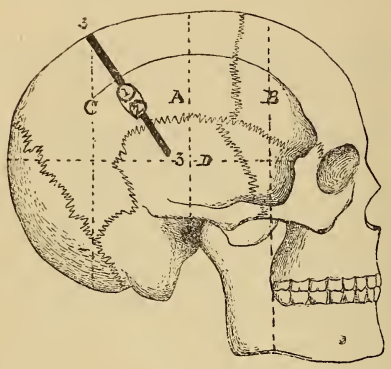
February 15. No improvement. My colleagues, Drs. T. A. McGran and H. T. Lyster, agreed with me that my patient was suffering from compression of the brain, evidently due to a blood clot, and agreed with me as to the importance of trephining. I directed the head to be thoroughly shaved, and washed with mercuric bichloride (1 to 500) and afterwards encased in a cap of several thicknesses of bichloride gauze, to be left on until the next day, the time designated for the operation.

February 16. In the presence of the class of the Detroit College of Medicine I operated. Before operating, however, I mapped out the head with aniline ink, first drawing

[1] Read, and patients exhibited, before the Detroit Medical and Library Association, April 16, 1888.

A, (Fig. 1) auriculo-bregmatic line, and at right angles with this line, D, the fronto-

FIG. 1.



lambdoidal line; then measuring posteriorly two inches and drawing another line parallel with A would give a space in which is found the fissure of Rolando 3–3. Our patient at this time was in a deep stupor, no stertor, complete paralysis of left arm and leg, pulse 38, and temperature normal. The pupils responded feebly to light. The point determined upon for trephining was midway over the right fissure of Rolando, the supposed motor area of the arm, 3–3; after producing anæsthesia with chloroform, a free crucial incision was made through the scalp and similarly through the periosteum, reflecting it back from the skull. On removing the first button of bone (2) a dark mass of coagulated blood protruded through the opening, and in order to facilitate the better removal of coagula I removed another button (1) and chiseled away the projecting bone on each side, thereby making a good-sized oval opening, which enabled me to readily introduce a lithotomy scoop, with which I took away four ounces of coagulated blood. The cavity was thoroughly irrigated with bichloride (1 to 1000) and packed with a continuous strip of iodoform gauze, leaving a piece of it projecting (for drainage) from the most dependent portion of the wound, which I closed with a continuous catgut suture, covering the whole head with a thick bichloride gauze cap. Before the patient was taken from the operating table there was manifest return of motion in the arm.

February 17. Passed a comfortable night; pulse 80, temperature normal, with increased motion of arm and leg; could answer questions fairly well. The dressing was renewed, as there had been considerable oozing during the night.

February 18. There has been gradual improvement since yesterday, without rise of temperature. He informs me that on the day that he was taken to the police station, he and some other fellow-workmen jumped from a scaffold which was giving away, a distance of about ten feet. This occurred at 2 P. M. He continued to work until 5 P. M. without inconvenience. While going home he observed that he could not hold his dinner-pail in the left hand, and shortly after this had no further recollection of anything until the morning following the operation.

February 19. I found him on entering the ward sitting on the edge of his bed; motion in the leg was increased, and his grip of the left hand upon mine was quite appreciable. Incontinence of urine had entirely disappeared. The dressing and iodoform gauze drain were removed, and the latter was replaced with several strands of catgut.

February 24. Patient walks about the ward; renewed the dressing, as there was still a slight oozing.

He continued to improve, and left the hospital March 15, 1887, with the wound entirely healed, and function of arm and leg fully restored, I have seen him several times since, and he is now as well as ever.

Trephining for Extensive Fracture and Depression; Hemiplegia; Aphasia; Recovery.

Case II.—Ambrose McNamara, aged 11 years, entered St. Mary's Hospital, Feb. 18, 1888, with the following history: On the afternoon of February 16; he fell from a building, a distance of twenty feet, striking upon his head. He was unconscious for about half an hour; during the night he vomited frequently small quantities of blood.

February 17. Was delirious at times, complaining of severe pain in his head, and during the night he lost the power of speech.

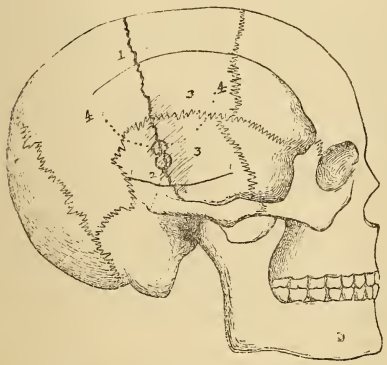
February 18. His symptoms growing worse, his physician, Dr. J. F. Encke, directed that he be sent to the hospital, where I first saw him. At this time there was hemispasm of the left arm, and turning of the eyes to the left. He would start suddenly when spoken to, and attempt to get out of bed. He had full control of his bladder, but had had no movement from the bowels since the accident. One drop of croton oil, however, acted quickly, producing free catharsis. The pulse was 80, and temperature 100.5°; pupils contracted, but responded to light. The entire scalp was greatly swollen,

and pitted on pressure. The point of greatest sensibility seemed to be just above the right ear, yet it was impossible to detect either fracture or depression of the skull. The head was shaved, washed and an antiseptic cap applied, together with an ice bag.

February 19. Passed a restless night, although full doses of bromide of potassium and chloral hydrate had been given. Hemispasm with hemiplegia of left arm and leg was now complete; pulse, 90; temperature, 102°; vision incomplete, and complete aphasia.

At 4 P.M., assisted by Drs. J. F. Encke, W. E. Clark and several medical students, I made a curved incision, with concavity towards parietal eminence, as indicated in Fig. 2 by dotted line (4–4). I found, how-

FIG. 2.



ever, that to expose the depression (3–3) and extent of fracture, it was necessary to extend my incision downwards (5). Reflecting back the periosteum, it was discovered that the fracture extended vertically from just above the external meatus to the parietal eminence, and transversely through the whole width of the squamous portion of temporal bone (1–1–1). There was a marked depression (3–3) in front of the vertical fracture. Removing two half buttons (2) with the trephine, and chiseling off the projecting bone, I succeeded with the elevator in lifting up the area of depression. The dura mater was deeply injected, and under it could be seen considerable coagulum. This was removed by cutting through the dura mater and irrigating with mercuric bichloride 1-1000. Hemorrhage was slight, and easily controlled. The wound was closed with continuous catgut suture. Several strands of No. 4 catgut were used as a means of drainage, extending from within the dura mater out, and the whole was covered with a thick bichloride gauze cap.

February 20. Pulse, 80; temperature, 99.8°. Has passed a comfortable night. I renewed the dressing, as there had been considerable oozing.

February 21. During the last twenty-four hours the patient has had two slight convulsions; pulse, 86; temperature, 99.5°. Spasm of the arm disappearing, with evidence of movement in the arm and leg.

February 23. Has been gaining gradually for the last two days; asks for a drink, and constantly (when not asleep) crying for something to eat.

February 27. Is able to sit up in bed; temperature normal. There is a marked improvement in speech and motion of the arm and leg.

March 2. Not so well. Temperature 99.5°. Eats and sleeps well, however. Ordered wound redressed.

March 6. After redressing of wound the temperature fell to normal, and has remained so ever since. He is now able to walk about the ward.

March 9. At the earnest solicitation of parents was allowed to go home. Wound nearly healed. At the present writing, he has been going to school for two weeks, and appears before you in perfect health.

Trephining for Traumatic Epilepsy; No Epileptic Seizures since Operation.

Case III.—T. Byerenski, Pole, aged 32 years; in June of 1887 was struck on the left parietal eminence with the end of a wagon-tongue. The blow caused unconsciousness for upwards of half an hour. He made a good recovery, but in October had a fit lasting for ten minutes. Since that time he has had several attacks—over a dozen in number—the last one on February 14, 1888. These attacks as described by the patient and his friends, were without doubt epileptiform in character. He gave no history of epilepsy previous to the injury, hereditary or otherwise, and was always in good health.

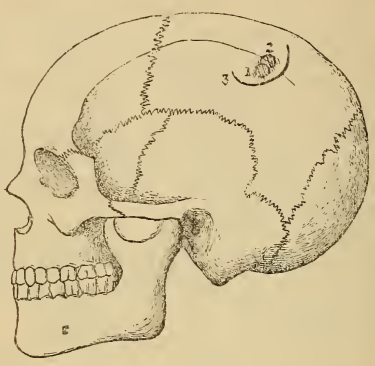
He entered St. Mary's Hospital, February 19, and was prepared for the operation as in the previous cases. At the seat of injury there was a circular depression three-quarters of an inch in diameter and one-fifth of an inch in depth.

February 22, made circular incision as indicated by line (3–3) Fig. 3, and reflected periosteum. First button (1) removed was directly over the centre of the depression; finding that there still existed above a portion of depressed bone, I removed a three-quarter inch disk of bone. The wound was drained and dressed as in the preceding case.

February 23. Dressing removed on account of oozing. Temperature normal.

The case progressed favorably, and the patient was discharged from the hospital, March

Fig. 3.

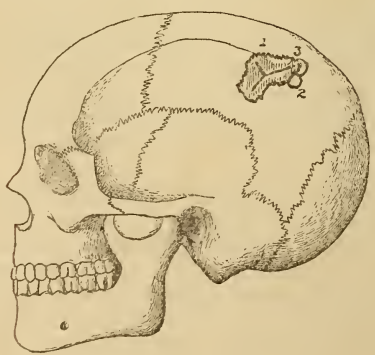


16, with the wound entirely healed. He is now back at his former work, and has not had the slightest symptoms of a convulsion since the operation.

Trephining for Compound and Depressed Fractures of Skull; Recovery.

Case IV.—J. Shemanski, aged 17, March 31, 1888, while attempting to steal a ride on a freight train, was thrown, and struck upon his head, rendering him insensible. He was picked up and taken to his home near by, when in about half an hour he recovered consciousness. His physician, Dr. L. H. Johnson, on being called, summoned me, and I saw him about two hours after the accident. There was a circular-shaped scalp wound about three and a half inches in length, just above the left parietal eminence. Laying back the flap I discovered an irregular-shaped fracture two inches in length, and depressed fully half an inch (1, Fig. 4), so that I could easily put the ball of my thumb in the depression.

Fig. 4.



He had fully recovered from the concussion. Neither he nor his friends seemed to realize the seriousness of the case, and it was with considerable difficulty that I could get them to consent to operative interference. The head was shaved and prepared as in the preceding cases. The opening through the scalp was sufficiently large to permit, after first reflecting the periosteum, of the removal of two half-disks (2–3), at the outer border of the depression, and several spicula of bone. With considerable effort the depressed bone was restored by means of the elevator to its normal position. The drainage and dressing was applied as heretofore described.

April 1. Temperature normal, and the dressings, thoroughly stained from the oozing, were removed and re-applied.

April 2. Found him, contrary to orders, sitting up; but without an unpleasant symptom.

April 16. To-day the dressings were all removed, and the wound found entirely healed. In this case there was no manifestation of an untoward symptom after the first dressing.

I forgot to mention that an ice-bag was applied to the head in all these cases for several days, except in the last case. You will observe, by the several buttons of bone which I exhibit to you, that I neglected to replace them. In my next report of this class of cases if I should be so fortunate as to have any, I hope to be able to present the patients with their skulls intact, by the immediate re-implantation of the pieces of bone removed.

The importance of surgical interference in lesions of the brain is conceded by the representative surgeons of the world, and although I can add but little to surgical literature upon this subject, I feel that in presenting these cases I have at least added a mite of evidence confirmatory of the good work that has been done in this direction during the last few years, and in reiterating the thoughts of others incite you to belief in, and further investigation of, this important subject.

Dr. John B. Roberts, of Philadelphia, in an admirable paper [1] upon "Operative Surgery of the Human Brain," divides the lesions of the brain that we have to contend with as follows: "(*a*) Cranial fractures; (*b*) intracranial hemorrhage; (*c*) intracranial suppuration; (*d*) epilepsy following cranial injury; (*e*) insanity following cranial injury; (*f*) cerebral tumor. The cases that I have presented here to-night are illustrative of cranial fractures, simple and compound, with some of the concomitant symptoms—intracranial hemorrhage and epilepsy.

[1] Annals of Surgery, Vol. II, pages 1–110, 214.

In case 1, in which a blood coagulum was removed, there was no history of traumatism until after the operation was performed, and we had to rely entirely upon objective symptoms as to the nature of the lesion, whether it might be hemorrhage, abscess, or tumor, while as to the site of lesion we were guided wholly by our present knowledge of cerebral topography, a partial diagram of which is exhibited in Fig. 1. The result certainly justified the means employed for relief.

Case 2 was also somewhat obscure, although we had the history of a fall, yet it could not be made out whether the symptoms of compression were due to fracture or hemorrhage, or both. Here again, we were largely guided by cerebral localization. I forgot to mention in the report of this case that the patient is left-handed, which will account for the aphasia, as aphasia in left-handed persons is due to the lesions upon right side of the brain.

Trephining for traumatic epilepsy has been robbed of its terrors since the introduction of antiseptic surgery, thereby justifying an operation when any depression of the skull can be traced as the direct cause of this terrible malady, for if relief or a cure is not effected the danger is *nil.*

Case 3, as has already been stated, has had no return of fits, yet the permanency of relief can only be determined by further time.

Case 4 was a typical one of compound fracture of the skull, and although no brain symptoms were present, and he would have probably got well under the strict maintenance of antisepsis, yet I felt justified in doing what was done, thereby preventing what occurred in case 3, although the depression in that case was considerably less than in case 4.

Abscess of the brain has been quite satisfactorily treated in the last few years by incision and drainage, a number of successful cases having been reported during the last year. A noteworthy case of removal of an intracranial tumor by Dr. Weir, and reports of similar cases by Horsley and others, are among the recent achievements of surgical art.

In conclusion, effective operations for the relief of brain lesions require: *First*, A thorough knowledge of cerebral localization, the details of which can be found in an article by Horsley entitled, "A note on the means of topographical diagnosis of focal diseases affecting the so-called motor region of the cerebral cortex." They may also be found in an article by Seguin, in Pepper's "System of Medicine," vol. v, p. 94. *Second*, A thorough knowledge and appreciation of antisepsis, together with efficient drainage.

BROWN-SÉQUARD ON CEREBRAL LOCALIZATIONS.

BY E. P. HURD, M.D.,
NEWBURYPORT, MASS.

This article is called forth by the paper of Dr. C. E. Brown-Séquard in the *Forum* for April, 1888:

I am sorry that the eminent neurologist thought it desirable to write such an article in a popular review, for not one non-medical reader in a thousand can understand it, and all that the ordinary reader will be likely to make of it is that there is a tremendous feud and no agreement whatever among physiologists, and that no advance has been made, or is likely to be made in cerebral physiology. Neither of these propositions is true. There is general agreement among authorities on cerebral physiology and there has been progress made.

Dr. Brown-Séquard is an amiable gentleman to whom the medical profession is indebted for many valuable discoveries. He was the first to publish the effects of galvanization of the sympathetic nerve, showing that contraction of the blood-vessels, diminution of blood, and decrease of the vital properties follow. These phenomena are just the reverse of those that succeed section of the sympathetic. He was also one of the first to trace to their origin in the spinal cord, those fibres of the sympathetic going to the blood-vessels of various parts of the head, and is the author of many ingenious and more or less probable explanations as to the influence of the nervous system on nutrition and secretion, and also as to the relationship of the vasomotors to the production of many diseases, as reflex paralyses and epilepsy.

Dr. Brown-Séquard's discoveries respecting the paths of sensory and motor impulses in the spinal cord and mesocephalon, respecting the effects of excitation of the anterior roots of the spinal nerves, the functions of the gray matter of the cord, the conductors of sensory impressions and their decussation in the cord, etc., are now parts of the history of medicine, and have given him a place among the great men of this century. He who demonstrates one scientific truth is a benefactor; to Brown-Séquard we are indebted for many.

But if Brown-Séquard is high authority on certain parts of the nervous system, he has certainly not distinguished himself in cerebral physiology or pathology, and I am not aware of a single great discovery which he has made in these departments of study.

While he has taught us much that is useful respecting cerebral inhibition, if any real progress has been made in the localization of function in the brain it has not been through him, for here he has had but one mission to perform, that of an obstructionist. In fact, eleven years ago he modestly announced his intention to be "to change almost (*sic*) entirely the physiology, normal and pathological, of the encephalon."[1] In his recent article in the *Forum* he affirms that since 1870 he "has been hard at work to show the untenableness of these [localization] views." From this we infer that the discovery and announcement of truth was not so much his object as the defence of views and opinions formed in the earlier and more plastic periods of his life, and to which he meant obstinately to adhere, despite all facts to the contrary. Like the patron of Alceste in Racine's play, that "*ésprit contrariant qu'il a reçu des cieux*" manifests itself in all his late writings: "*Le sentiment d'autrui n'est pas fait pour lui plaire.*"

In 1876 he delivered before the Royal Society of London a lecture "on the appearance of paralysis on the side of a lesion in the brain," in which he controverted the prevalent doctrine—generally admitted to have few exceptions—that a paralysis due to cerebral disease is on the side opposite the lesion. He cites in support of his thesis over three hundred observations, but, as Seguin observes,[2] most of them are old cases, *i.e.*, cases reported before modern cerebral anatomy was understood, and many of them are related by men utterly or relatively unknown. "Furthermore" we quote from Seguin: "any one who has worked much in the post-mortem-rooms will appreciate how easily *right* is wrongly written, where *left* is meant, as a brain is turned over and around for examination. Consequently, we might claim the right to reject as worthless many of these three hundred cases. Suppose, however, that they are accepted as *bonâ fide* examples of palsy on the same side as an encephalic lesion, and that we compare them with the thousands of cases of classical hemiplegia on the side opposite the cerebral lesion, do we obtain a proportion greater than that observed in Flechsig's series of fœtuses, one to sixty? I think not."

Dr. Brown-Séquard formed his views of cerebral physiology at the time when the teachings of Flourens and Magendie were predominant. Flourens, interpreting certain physiological experiments and pathological observations which had to do with the artificial removal or destruction by disease of certain parts of the brain, saw reasons for the conclusion that there was no particular localization of function, that the whole brain was operative in the performance of psychical function (thought and voluntary action), and that, there being no physiological distribution of labor, but all the faculties and functions having their seat in every part, any portion of the cortex cerebri might, up to a certain point, perform the work of the whole. This doctrine, which certainly has had much to give it support, is essentially that held by Longet and Vulpian.[1] Brown-Séquard early modified it somewhat. There are, he believes, psychical (sensory, perceptive, voluntary) centres, but they are widely diffused; thus, for instance, the cerebral direction by which I am writing this sentence does not come from a motor graphic centre, a definite, localized CLE, if I may be permitted to refer to Charcot's diagram in the REPORTER for March 31, page 402, but from ganglion cells scattered all over the hemisphere and connected by association fibres.

Such a view of the cerebral functions is possible, but it is contrary to the whole analogy of nature, and to that specialization of structure and function which characterizes the evolution of all living beings. It is, for instance, much more in harmony with all analogy and with the law of evolution, to believe that an optical impression, for instance, pursues a definite course, a "beaten track," if the expression may be allowed, to form "cluster-localization," whether in the posterior part of the parietal, or in the occipital lobe, or in both, than that it runs along one fibre to a cell in the frontal lobe, along another to a cell a few centimeters further back, along another to a cell in the occipital lobe, and so on. In fact, it is hard to picture to yourself intelligibly Brown-Séquard's scheme, and when once fairly stated it seems hardly to need any other refutation than its own intrinsic absurdity.

Our best living neurologists come under the ban of Dr. Brown-Séquard's papal pronunciamento (see the *Forum*, April, 1888), and are rather contemptuously styled by him "cluster-localizers." Such men as Fritsch and Hitzig, Munk and Ferrier, Nothnagel and Charcot, some of whom are as careful experimenters and as good clinical observers, and have done as much for science as Brown-

[1] Archives de Physiologie, 1877, No. 2, p. 413.
[2] *Medical Record*, 1878, p. 482.

[1] Longet taught that the cortex was "inexcitable," a statement that subsequent researches have completely overthrown.

Séquard, are included in this denomination. I might allude to hosts of authorities both in Europe and in this country, who have accepted the doctrine of cerebral localizations as supported by convincing scientific evidence, and as in fact the only theory which satisfactorily explains the ever accumulating mass of facts. It is not only a theory which "explains facts," but it has proved itself to be a good working theory, and this is one of the best arguments for its validity. The regional surgery of the brain may now almost be said to be based on the modern doctrine of localization. A train of symptoms (Jacksonian epilepsy, monoplegia, etc.), points to a lesion by a spiculum of bone, or a tumor in a motor region of the cortex; the trephine is applied, and the spiculum of bone or tumor removed, with cure of the disease for which the operation was performed. An abscess of the occipital lobe causing hemiopia has been diagnosticated by the symptoms and the abscess opened, with improvement of all the symptoms therefrom resulting. Instances of this kind are legion, and readers of medical journals are sufficiently familiar with them.

To me nothing is more suggestive and full of interest than Prof. Yeo's experiments on monkeys. They show in the clearest manner possible "that after localized or limited lesion by means of the galvanic cautery of the surface of the brain, certain phenomena of paralyses may be predicted to occur, that these phenomena do actually occur, and that after death microscopical examination shows that strands of fibres proceeding from the damaged parts of the cortex may be traced down to the motor or sensory ganglia at the base of the brain, and thence downward through the spinal cord to the muscles paralyzed by the lesion." "No clearer evidence" says the London *Lancet* regarding these facts, "of the localization of function in the cortex of the brain could be desired."[1]

All these, and multitudes of like facts, it is convenient for Brown-Séquard to leave unnoticed, or dismiss with a sneer, for dogmatism and bigotry have taken possession of him. He has a theory which he must uphold at all hazards, a theory which has made scarcely a convert; he has seen certain facts at the autopsy, or in some of his numerous vivisections, which he thinks are contrary to the received views, and he does not seem to have asked himself, before proclaiming results so opposed to thousands of careful observations by quite as competent experimenters as himself, whether or not the observations which he records were so free from all possibility of error, so trustworthy and unimpeachable, as absolutely to settle the question under dispute. In no department of study are mistakes so likely to be made, or is absolute accuracy so desirable as in researches and examinations into the morbid anatomy of the nervous system. Thus, it seems almost certain that much that has been written by Brown-Séquard and others in opposition to Broca's localization of the speech centre is vitiated and rendered inconclusive by defective observation. This was especially true the first five years after the announcement of Broca's discovery, and during the unprecedented storm of opposition with which that announcement was greeted, even Trousseau was caught tripping by Broca himself, who found a spot of softening in a post-mortem specimen which the former had overlooked. In fact, by thousands of observations, the essential importance of the posterior extremity of the third left frontal convolution for the exercise of the function of speech, remains in the language of Nothnagel at the late Congress of Internal Medicine, at Wiesbaden, as also of his co-reporter Naunyn, "unattackable," and this we may regard as settled, despite Brown-Séquard's sneering remark that "a lesion in any part of the cerebrum may cause aphasia." It seems to me that Brown-Séquard's great mistake is in confounding the results of simple inhibition from irritation (which results are generally temporary) with the more formidable and more permanent results of destructive lesion.

But I have already exhausted the space which I intended to devote to this subject. Dr. Brown-Séquard is now regarded by the profession as behind the times, and nothing which he writes makes much impression on medical men generally, who know how observation and judgment may be warped and vitiated by inveterate prejudice. His statements, made with so much magisterial authority, and reading so much like a papal *ex cathedrâ* deliverance, would, if true, demolish all the notions of cerebral physiology which labors of so many painstaking workers during the last two or three decades have built up, for every theory must give way before opposing facts; but are his iconoclastic statements to be trusted? I, for one, hesitate to believe them. When a man tells you that your next-door neighbor, alongside of whom you have lived for fifteen years, is a scoundrel, a thief and a liar, and you have always found him sincere, honest and truthful, you are slow to believe the statement, and you wait for stronger testimony. So, if a great physiologist, with the most imperturable confidence, assures you that all that you have learned about the

[1] London *Lancet*, American edition, 1882, p. 298.

cerebral functions the past fifteen or twenty years is "moonshine"; that the distribution of function in the cerebrum is simply *chaotic;* that the whole is in every part, and every part in the whole, you will demand proof stronger than his word for it, even though he declares that his experiments have overthrown every one of Ferrier's propositions, or though he appeal to observations, many of which were made years ago, unchecked and unverified by experts, and which may have been hasty, superficial and incomplete.

The matter shapes itself in my mind in this way: If A has followed B as a sequence in hundreds and thousands of instances, and when B does not exist, A is absent, I affirm a law of nature that there is a casual connection between the two. If some eminent authority steps up—Brown-Séquard, for instance —and says: "In my experience, and in the observations of so-and-so, there is no such concomitance," I cannot help doubting the accuracy of that experience and those observations. I place my faith and confidence in the uniformity of nature more than in any one man's testimony, and while there may be exceptions to a general law (and I believe that there may be with regard to the speech centre in the cortex, which may in rare instances occupy a different area), yet absolute *contradictions* do not exist in nature, otherwise:

> "This pillared firmament were rottenness,
> And earth's base built on stubble."

DISEASES OF THE SOUTHERN NEGRO.

BY J. WELLINGTON BYERS, M. D.,
CHARLOTTE, NORTH CAROLINA.

One of the most conspicuous and remarkable facts associated with the development of the medical history of this country is the entire absence of anything like a special treatise upon the peculiarities of disease as manifested in the negro race. The eight millions of this people that principally inhabit the Southern States certainly present many racial contrasts which are vastly interesting and important, and are well worthy of more attention than has been heretofore bestowed upon them. It is a well-known observation that certain individuals are occasionally met with who are but slightly vulnerable to the influences of certain diseases—that when attacked they easily get well; while other, though rarer, instances are found in which the exemption is so manifest as to amount to entire immunity. These same observations can be made to apply with equal force and appropriateness to the peculiarities and susceptibilities which are known to characterize certain races: the total escape of some, as was at one time the case with the negro as regards yellow fever, malaria, and tuberculosis; the modification of others in degree, as witnessed in scrofula and consumption among Indians; and lastly, the perversion of the special type, as is seen in the Irish and German nations. The modifying and diversifying influences of race, climate, social condition and environments in general, upon the production, development, and results of disease are obvious. That they certainly have an important agency in controlling morbid phenomena, and do produce great difference in their manifestation, is equally true. To one who has not given special thought to this department of knowledge, the peculiarities that can be enumerated as pertaining to the colored race alone would be calculated to astonish. Anthropologists pretty generally concede that this people, at least in its natural habitat, is about the lowest stratum in all human kind. Naturally, when we come to consider its features in comparison and contrast with such a race as the Anglo-Saxon, we can but expect to find the most marked divergencies.

For the three and a half centuries previous to 1850, there were brought to this country as slaves nearly fourteen millions of Africans. These were representative of one hundred and thirty-seven different tribes, and there now remain living only about five hundred people that composed this original stock. As represented by a historian of their own race,[1] these came from the lowest classes of society, and were composed of the diseased, barbarous and criminal elements. With impartiality the whole mass may now be said to have passed through at least several generations, and their best and worst features to be fully manifest, if not matured. The Southern States now have a population with a ratio of eight whites to five blacks, and the death rate of the former is somewhat less than fifteen per 1,000, and of the latter a little more than eighteen per 1,000. The chief source of mortality in negroes who have passed the period of infancy, is tubercular diseases. The report of the U. S. Army Surgeon-general, for the year 1884, shows that four times as many deaths occur among the blacks, when affected with disease of the respiratory organs, as of the whites. For the whole country, the negro dies annually from consumption at the rate of twenty thousand,

[1] Williams, History of the Negro Race in America.

while the death from the same cause among the whites amounts to only fifty thousand. The proportion of the living in these two races is nearly seven to one, and they die in a ratio of about three to one. The material conditions that form their environment cannot furnish a reasonable basis for the great contrast presented by this announcement; there must be a superiority on the one hand, and an inferiority on the other, that transcends the usual influences that emanate from ordinary physical conditions. Is the negro inferior by nature, and does this inferiority rest upon sound philosophical principles, such as are permanent and unchangeable in the usual tide of affairs? From an experience that has been varied and extensive, I feel quite safe in saying that the colored race of this country is undergoing serious physical deteriorations as compared with the sturdy condition that they possessed previous to the civil war. The present generation is having a conflict with influences so debilitating and destructive of its physical and moral powers that the evidences of their seriousness are everywhere apparent. Any race of people which can, in a space of time that has been allotted it as freemen, double both its mortality and criminal rates—and the negro race has done this—is inevitably doomed to destruction unless there be immediate and radical changes in its methods of life. The mortality reports of six cities which are given at the end of this article will corroborate these assertions, and show them to be unexaggerated in the least.

Thirty years ago consumption in the pure negro was such a rarity as to be almost unseen in the medical experience of a lifetime. Statistics to-day show that deaths from this cause are in a ratio double that of the whites. Pneumonia, diseases of digestion, malaria, and diseases of the nervous system, all show a higher mortality rate in blacks; whereas in the past the exact reverse was usually true. This critical predicament of the physical condition of this race has already been too long disregarded, and the immediate and remote effects of this neglect and violation of the important laws of sanitation and hygiene among them has become so deeply rooted upon their constitutions, that nothing short of their uttermost degradation and ruin seems at all evitable. From a sociological standpoint a people that is naturally callous to all beneficent and moral impulses which tend to elevate its physical, moral and intellectual faculties, is sure to present a proportional amount of depravity. The negro race is still influenced by the relics of its hereditary barbarism. Charms and witchery among the moral classes still persist in an important place, they believing in their power to produce evils and misfortunes. Added to these infirmities, the negro has the degrading vices that naturally arise from circumstances which surround all such grades of civilization as ours.

The weakest members of the social body are always the ones to become contaminated, and sooner or later succumb to the devitalizing forces of intemperance, disease, crime and death. The negro is peculiarly unfortunate; he has not only the inherent frailties of his nature to war against—instincts, passions and appetites; but also those nocuous, seductive, destroying influences that emanate from free institutions in a country of civil liberty.

What has been written would seem to indicate but one issue for this race of people, and that is too palpable to dwell upon. The causes of the shortcomings of the negro and the avenues through which he reaches them are alike plain. Future progress for him means a thorough and immediate change in the purposes, resources, and methods of life. He needs to preserve his physical powers; he needs temperance in all of its forms: frugality, moral courage and a better system of mental training, one more in concert with his capacity, which would fit him for a proper appreciation of his social and physical status. He must withal endeavor to help himself, and establish in his own race those qualities and aptitudes that go to form character, and a being that will be capable of employing and enjoying the exigencies of moral and physical law. He has been a child too long; he needs to be thrown upon his own resources, for no race can progress so long as it is indulged by a parent with the capital resources of the United States Government.

The brief space here allotted will not permit of more than casual mention of some of the most characteristic features associated with diseases in the colored race. The causes of the rapid deterioration that threaten this people are found to lie in its high sensuality and intemperance, which lead to pauperism, crime, and insanity; its total disregard for the laws of sanitation and hygiene, which conduces to miasmatic, diathetic and enthetic diseases. The negro's capacity for race preservation and perpetuation is remarkably low. The average increase for the white race during the three last decades is not much below 40 per cent., while that of the negro has scarcely been twenty-five. Of the entire criminal class of the whole country, the

negro forms nearly twenty-five per cent. From this much it will be seen that there are inequalities greater than skin, brains or wealth, such as are plainly out of the power of any social arrangement to alter. Evolution by force of external environments may yet do much, but not all; there are the internal relations, which are too far removed from influences capable of making any durable, transmissable alterations, which must continue to exist as a barrier to all transitions of one race into the life of another. These are as fixed as the laws of the universe. Miscegenation is taking place at a less rate than ever, and each year sees it growing smaller.

Civilization seems to increase their liability to diseases of the special sense and nervous system. Dr. Andrews, of Buffalo, has recently said that while the negroes increased in the last decade (1870 to 1880) at the rate of 35 per cent., insanity increased among them at the rate of 26 per cent. This proportional increase of insanity far exceeds that in the whites. It is predicted, with reasonable justification, that by the year 1890 the insane among the colored people will be double what they were in 1880.

Delirium tremens rarely occurs among negroes; the reason of this is attributable to their physical inability to stand prolonged debauch, they are soon forced to give up and the system never reaches that point of exhaustion at which delirium sets in. The opium habit is exceptionally rare among them, and suicidal tendencies are very infrequent. Both sexes are fond of, and are addicted to, the use of drink and tobacco. The women are very prolific, twins are common, and the still-born are twice as common as in whites. Parturition is usually easier, though dystocia is frequent; a woman will be confined one day and up at her duties the next. Uterine disease is common, a great many suffer with fibroid growths, prolapse and displacement. The negro child is not black at birth as is popularly thought, but of a brownish copper-color, resembling closely the color of a white child, but it darkens gradually and in a few days is of the usual tint. The children mature faster, get their teeth earlier and decline more quickly than whites. The diseases of dentition are especially fatal in blacks, one-half of their death-rate being due to this cause, which is probably owing to the bad quality of diet, poor attention, and unhealthy surroundings.

Worms in children are common and often fatal. Rickets is a characteristic, nearly all negro babies are bow-legged; this deformity is usually overcome without special attention. Congenital deformities are rarer in this people than in the whites; talipes in any form, spina bifida, cleft palate, epispadias, hypospadias and exstrophy of the bladder are of the most unusual occurrence. The typical negro is below the average height of the white race, he is muscular, but prone to obesity as age advances. His vision as to distance appears to be superior, and he is signally free from the usual order of eye and ear diseases. Tetanus is common, and in most instances fatal; trismus nascentium is more frequent than in whites, and invariably fatal.

The negro is especially free from skin diseases; this is most marked in those incident to dirt; they rarely bathe their bodies and are notorious for their opposition to water. The eruptive fevers are the more fatal in the form of sequelæ; the mortality from measles is high; malaria, which at one time had no terrors for this people, stands high on the death dealing diseases of this race, and the mortality of negroes from this cause is double that of the whites.

The negro's digestion is superior; he is truly omniverous, though gastric disorders are not uncommon, which are doubtless due to an excessive fondness for, and an abuse of, the hydro-carbon foods. They take large quantities of cathartics with impunity; piles are infrequent and fistulæ are common. They are easily affected by the sight of blood, both sexes are subject to and easily faint, are stoical in great pain, and unmindful of death when stricken with fatal disease. They bear anæsthesia well, stand surgical operations better, and bleed freer than whites. Keloid is very common, carcinoma rare, and malignant growths are usually in relation to the skeleton (osteo-sarcoma) as pointed out by Tiffany. Stricture is often met with, nearly always as the result of neglected gonorrhœa; syphilis is common, both the hereditary and acquired forms, and is, as a rule, more amenable to treatment than in the white race. One important question associated with the statements set forth in the mortality tables of this paper, is how far the excessive mortality is due directly to the influence of racial characteristics, that is, to less actual vital capacity to resist disease and death, or to peculiar susceptability to certain forms of disease. We are qualified to state that the observations here presented are sufficient to warrant the assertion that the high rate of mortality of this race is certainly due more to inherent weakness or physical degeneracy than to any special faults in the environment. The data are spread over too wide a scope of territory

to justify a belief in special local defects. The rural death-rate will be found relatively just as excessive as the urban. Therefore we must conclude that this race is undergoing serious physical decay, and one of its racial characteristics is general inferiority as compared with the white race. The statements here presented show the average and ratio of the death-rate for certain cities of the Southern States. The reports of Richmond, Washington and New Orleans show uniformly a higher death-rate for blacks than whites.

REFLEX COUGH FROM PREGNANCY.[1]

BY GEORGE E. SHOEMAKER, M.D.,
PHILADELPHIA.

All of us have seen cases in which, in the early months of pregnancy, the stretching or pinching of nerve fibres in the uterus has been interpreted, through the medulla, in the muscles correlated in vomiting. All of us know of the reflex sensations, of the vasomotor and trophic changes, of the mental phenomena, and the occasional bowel complications of early pregnancy. Instead of these, in the case which is here related, the sensory impulse travelled from the uterine plexus through other sympathetic paths to the cord, to the medullary centre of the pneumogastrics and out along that and other nerves to the apparatus involved in a cough. The case was as follows:

Mrs. X., aged thirty, very muscular, almost an Amazon in physique. General health apparently perfect. She has had two children, three miscarriages, and is now in the seventh month of her sixth pregnancy. It was in 1885 that she was first seen, while bleeding from a miscarriage at two months. She then stated that for several days before the uterus emptied itself, she had been troubled with a cough, without expectoration, coming on whenever she laid on her back. It ceased with the loss of the uterine contents.

Second attack.—Six months later, having been well in the interval, she was again pregnant at two months. No symptoms causing distress now appeared, except a cough, which, for two weeks, had troubled her as soon as she lay down at night, continuing at intervals until she arose, when it ceased almost entirely for the day. No pain, expectoration, or signs of respiratory irritation. A small dose of bromide and chloral, with hyoscyamus, taken in the evening, at once relieved the condition, which, however, returned immediately if the medicine was omitted. The tendency to cough subsided as pregnancy advanced, and the subsequent labor was normal.

A *third attack*, exactly similar, occurred when she again became two months pregnant, in January, 1888. The cough continued for two weeks before she applied for relief, and then was at once removed by the same treatment as before, a sedative given in the evening.

The patient has never had vomiting of pregnancy. Before coming under observation she had had one child and two miscarriages. History of cough with these was uncertain. Examination showed no malposition or flexion of the uterus, and no laceration or erosion. The organ was freely movable, with no lateral tenderness; the ovaries normal. The diagnosis then, in the three successive pregnancies under observation in this patient, has been reflex cough from gestation, without other symptoms.

That large numbers of the symptoms which we daily see are reflex, it is easy to say, but it is by no means as easy to determine the paths of these reflexes; or to see why, in one case, one path should be taken, and in another case another. With the same stimulus to the same group of nerve filaments, the result will be interpreted in vastly different effects. So intricate, too, are the relations of different parts of the nervous system, and so diverse the influences which serve to switch off, as it were, the ongoing nerve impulse in this direction or in that; that in many instances we are obliged simply to record facts, and leave unexplained, because yet unknown, steps which lead to their development.

It will be remembered that the pneumogastric nerve has an extremely wide distribution and connection. That, besides going to the heart, and besides influencing the vasomotor system through the medullary vasomotor centre, it goes to the lungs and larynx, to the pharynx and œsophagus; that it is connected with the external auditory canal, and with the meninges of the brain; that it goes to the stomach and intestines, to the liver and spleen, and, in short, to most of the abdominal viscera. Its connection with fibres of the sympathetic in the abdomen, enables it to receive impulses from organs such as the uterus, with which direct connection has not yet been fully traced. While most cough is well known to be reflex from stimulus to pneumogastric fibres in lungs or larynx, the same result may follow a stimulus applied almost anywhere in the distribution of this nerve.

[1] A paper read before the Philadelphia County Medical Society, May 9, 1888.

The members of the Society need only be reminded of the cough which occasionally comes from putting a speculum in the external auditory canal, and of that which sometimes follows a disordered stomach; while the writer has now in mind a case of persistent cough, which has resisted treatment for years by the best specialists, and which is, in his judgment, probably due to irritation of the meningeal branch of the pneumogastric in the posterior cranial fossa. Why the connection with the vomiting apparatus offers the easiest outgoing motor path from the medulla for the reflex impulses from the pregnant uterus, we do not know. The reflex sensory, trophic, and vasomotor paths in pregnancy seldom, if ever, lead to the stomach. In the case which has been narrated, the easiest path from the medulla led to the respiratory system, probably as the result of idiosyncrasy alone.

PRELIMINARY NOTE ON SULPHONAL AS A HYPNOTIC.

BY J. C. WILSON, M.D.,
ATTENDING PHYSICIAN TO THE PHILADELPHIA HOSPITAL, AND
R. HUTCHINSON, M.D.,
RESIDENT PHYSICIAN TO THE INSANE DEPARTMENT, PHILADELPHIA HOSPITAL.

Upon the appearance of Kast's communication upon sulphonal, *Berliner klin. Wochenschrift*, April 16, 1888, we ordered a quantity of the drug through Mr. F. E. Morgan. It was received May 24th, but the amount, owing to circumstances beyond Mr. Morgan's control, being only 275 grains, was far too small for any extended or satisfactory clinical observations. We therefore decided to test it in a few cases of the severer forms of insomnia and maniacal excitement. This plan was adapted to avoid in the first place, the errors incident to a limited number of observations in cases of mild, and therefore often intermittent insomnia, and in the second place to aid in determining the range of cases in which the effects of the drug may be investigated in the future. The result was, in view of the reports of Kast and Rabbas, (see editorial *Medical News*, May 26, 1888) a disappointment. It has, however, the peculiar value of negative results in general, and is for that reason published. What doses of sulphonal will induce sleep in cases of this kind, or whether or not sulphonal in any dose or in any doses, unattended by the risk of toxic effects, remains to be determined.

Case I.—As a control test to the subsequent investigations, gr. xxv of the above mentioned drug were given to a healthy male adult upon retiring, with no more effect than his accustomed normal, peaceful repose, and with no ill after-effects whatever.

Case II.—P. F., male, 48 years old, native of Ireland, laborer, was first admitted to the Insane Department of the Philadelphia Hospital January 10, 1885. On April 23, of the same year, after the fire, he was transferred to Norristown, where he remained till March 23, 1887. He is a case of terminal dementia, probably of specific origin, and with a history of alcoholism and the opium habit. Patient has marked delusions of a depressive character, and at irregular periods has acute exacerbations, when he becomes very restless, sleepless and noisy, continually crying out and using the most profane language. The spells lasts in varying intensity for days and sometimes for weeks. He has been given nearly every sedative and hypnotic in the domain of medicine, with only partial results.

Doses of hyoscine gr. $\frac{1}{48}$ *per orem* and hypodermically, and repeated every three hours have but little effect. Morphia gr. $\frac{1}{4}$, chloral gr. xxx and potass. bromide gr. 90; and repeating morphia gr. $\frac{1}{6}$, chloral gr. xv and potass. bromide gr. lx, in an hour have only temporary effect. Paraldehyde ʒij repeated every three yours, the same.

The fluid extract Jamaica dogwood in ʒiij doses, repeated every three hours, with about the same results. Each of these drugs and their combinations in the above mentioned doses have only seemed to quiet him partially and for a short time.

On May 25, 1888, he was given, at 3.30 P.M., gr. xxv of sulphonal, with no effect. On the 27th, at 7.30 P. M., he was given gr. lv, with no perceptible result. There were no ill effects following either of these doses.

Case III.—C. F., male, 45 years old, native of Germany, shoemaker, was admitted to the Philadelphia Hospital, Insane Department, on April 18, 1888. He is a case of paretic dementia, and on admission was in a maniacal state, which has somewhat subsided, but is still very restless, both day and night, spending much of the time pacing up and down the room in which he has to be confined, with mufflers and canvas jacket on, to prevent his wanton destructiveness.

At night he is usually very sleepless, restless and talkative, but as a rule receives no sleeping potions. On May 25, he was given gr. xx of sulphonal at 3.30 P.M., with no noticeable effect whatever.

Case IV.—J. F. M., male, 50 years old, native of Germany, laborer, was admitted to the

Insane Department of the Philadelphia Hospital, on May 19, 1888. A case of paretic dementia, not violent or noisy, but with very restless and sleepless nights. He is constantly talking or muttering to himself, and has occasional spells of laughing.

When put to bed on the evening of the 27th, he received gr. xxx, of sulphonal, which was not followed by any more perceptible quiet or sleep than on former nights.

Case V.—Male, 46 years old, in the preataxic stage of tabes dorsalis; business worries; habitual bad sleep; frequent excesses in drink, followed as a rule by great mental and physical depression and prolonged inability to sleep, often extended, despite large doses of chloral, the bromides, hyoscine, etc., for several nights in succession. Morphine hypodermically not well borne. May 25, after two nights of distressing wakefulness, took 15 grains of sulphonal at 6 P.M.; 30 grains at 7 P.M.; 15 grains at midnight, after which he slept quietly for two hours. May 26, took at 11 P.M., 30 grains, and slept continuously eight hours without interruption. May 27, took at 10.30 P.M., 30 grains without effect. This patient suffered from the gastro-hepatic catarrh, which usually follows a prolonged debauch, and took even liquid food with difficulty; much thirst and nausea; occasional vomiting. No aggravation of these symptoms and no effect whatever upon the pulse, respiration or temperature, followed the administration of the sulphonal. The preparation used in these observations was Merck's.

Kast made more than 300 observations in 60 patients with remarkably favorable results. These were chiefly cases of "nervous" insomnia in neurotic persons, or in patients suffering from organic brain disease, old people with poor sleep, the febrile insomnia of acute diseases, heart disease with sleeplessness, resulting from disturbances of the circulation, and in a single instance the remedy was tried in an old man suffering from senile dementia with active delirium. The result in this last case is not given. The dose varied from 1.0 to 3.0 grams (grains xv–xlv).

Rabbas, Assistant-physician in the Insane Asylum at Hamburg, used sulphonal 220 times in 27 patients in like doses, and reports favorable results, although there were some few failures (*Berliner klin. Wochenschrift*, April 23, 1888.) These were cases of mania (7); hysterical dementia (1); melancholia (9); epileptic dementia (1); senile dementia (1); paretic dementia (3); recurrent mania (1); periodical melancholia (4).

These observers regard sulphonal as superior as a hypnotic to chloral, paraldehyde, the bromides, amylene hydrate, opium, and cannabis indica. It is a pure hypnotic, and without disagreeable after-effects.

Baumann, to whose researches in association with Kast the discovery of sulphonal is due, named it diethylsulphondimethylmethane. It is a member of the disulphon group, having the formula $(CH_3)_2{=}C{=}(SO_2C_2H_5)_2$. It crystallizes in large colorless plates, without taste or smell, fusible at 125–127°C., soluble in 18–20 parts boiling water and 100 parts of water at ordinary temperatures. It is also soluble in alcohol and mixtures of alcohol and ether. Given to dogs, it produces motor disorders, at first ataxic, later paretic, followed by deep and prolonged sleep. In waking, the animals were for a time unsteady, but quickly recovered, took food and seemed perfectly well. A small dog, after an excessive dose, died in convulsions.

The dose for an adult is 1–4 grams (gr. xv–lx). It may be given in water or mixed with fluid articles of diet. In these doses sulphonal has no influence on the digestive organs, nor on the respiration, circulation or temperature.

Society Reports.

ILLINOIS STATE MEDICAL SOCIETY.

THIRTY-EIGHTH ANNUAL MEETING, HELD AT ROCK ISLAND, ILLINOIS, MAY 15 AND 16, 1888.

First Day, May 15.

The Society was called to order by the President, Dr. W. O. Ensign, of Rutland.

Prayer was offered by the Rev. W. S. Marquis.

Dr. C. Truesdale, of Rock Island, Chairman of the Local Committee of Arrangements, delivered the address of welcome.

Dr. C. W. Earle, of Chicago, expressed the pleasure it afforded him to speak in behalf of the Society in response to a welcome to the city of Rock Island, which contained some of the most useful, active and able members of the State Medical Society.

Dr. Walter Hay, of Chicago, sent in his resignation as Treasurer of the Society, and the thanks of the Society were tendered to him for his very efficient services as Treasurer.

President's Address.

In his remarks, Dr. Ensign paid a glowing tribute to those who had preceded him in office, and alluded touchingly to the large number of deaths that had occurred during the year among members. He then dealt with the question of reorganization, and the plans and modes of holding the annual meetings. He thought the State meeting, occurring so shortly after that of the American Medical Association, detracted largely from its interest and attendance. The address touched further upon the relations of the State Board of Health to the study and practice of medicine in the State, favoring the limitation of the issue of certificates to practice to those only who could pass a successful examination before the State Board of Examiners. More thoroughness in all the preliminary branches of education was urged and recommended.

Report on Practice of Medicine.

Dr. Frank Billings, of Chicago, Chairman of the Committee on Practice of Medicine, said he was indebted to Dr. John Rauch, Secretary of the Illinois State Board of Health, for reports which indicated a satisfactory condition of the

Public Health for the Year.—Local outbreaks of diphtheria, scarlet fever, measles and typhoid fever have occurred at different places in the State. In no case has an extended epidemic of these diseases occurred. Croupous pneumonia had prevailed to an alarming extent during the winter. In Chicago the mortality has been greater than for several years.

Bergeon's Treatment of Phthisis Pulmonalis.—The treatment of this disease by rectal injections of sulphurreted gas in carbonic acid has received extended notice and discussion during the year. The expectations raised by the remedy have not been realized. The treatment has been thoroughly tested in the United States, and the almost universal opinion seems to be that it exerts no curative influence on the turbercular process, but does exert a palliative influence, diminishing the sputa, relieving the cough, night-sweats, thoracic pain, improving the appetite, and consequently the strength of the patient. These favorable conditions are temporary, however, and the time comes when the injections cease to have a good effect. In one case under Dr. Billings' care, treated with daily injections for more than two months, glycosuria suddenly supervened. The complication disappeared under appropriate detetic treatment and a cessation of the rectal injections.

The treatment is still in vogue in France and Germany, and favorable reports are made. Cornil and Bergeon have recently experimented with the gas on guinea-pigs. Six guinea-pigs were made to breathe the dust of dried tubercular sputa for twenty minutes daily for five days. Of these, three received no treatment, and three received daily rectal injections of the gas. Of the three which received no treatment, two died in ten days of broncho-pneumonia, and one died in fourteen days with phthisical cavities in the lungs. The three which received treatment remained well and playful. Of these, one was killed in four months, the lungs showing a cheesy deposit which contained tubercle bacilli. One was killed at the end of seven months and showed also a cheesy spot in the lung, but a less number of tubercle bacilli. A third was killed at the end of ten months and showed a calcified cheesy deposit without bacilli.

The aniline treatment of phthisis recommended by Dr. Kremianski consists of the internal use of antifebrine, grammes five to one daily, which is decomposed in the body into aniline, and of inhalations of oil of aniline in one of the aromatic oils. Dr. Bertalero reports successful results in eight cases. Dr. Billings has used the treatment in two cases with absolutely no benefit.

Treatment of Diphtheria.—The use of oil of turpentine in diphtheria has received a new impetus recently. Dr. C. Roesse, of Hamburg, has reported its use in sixty cases. Of these, two were one year old, five were two years old, five were three to five years old, ten were six years old, six were seven to nine years old, fifteen were ten to fifteen years old, ten were sixteen to twenty years old, six were twenty to thirty years old, and only one was over thirty years old. Only five died. Of these, two were one year old, were moribund when first seen, and died within a few hours. Two had the disease in a virulent form and lived only thirty-six hours, and the fifth was a poorly nourished boy of fifteen years old, who died in five days. The oil of turpentine was given in teaspoonful doses three times daily. As a corrective Dr. Roesse used spiritus ætheris, minims xvi, to each teaspoonful of turpentine oil. He also gave a tablespoonful of a two per cent. solution of sodium salicylate every two hours, had the patient use a gargle of a one per cent. solution of potassium chlorate, and applied ice-bags. He noted the following results: (1) The fever and frequency of the

pulse diminished rapidly. (2) The subjective difficulties, such as headache and difficulty of swallowing were soon relieved. (3) The duration of the disease was greatly shortened. (4) The local symptoms improved, in most cases as soon as the first dose had taken effect. The turpentine was used cautiously in anæmic and weak patients, and in cases of cardiac troubles. In strong patients the heart's action was carefully noted. The patients were given strong bouillon or beef-tea, port wine, and milk. Ice-water was given for thirst. The turpentine was withheld as soon as the patient was free from fever and the local symptoms had improved. Usually four or five drachms were given during the disease. Dr. Roesse states that he has never observed any signs of turpentine poisoning as a result of this treatment. The oil of turpentine treatment gives promise of a successful future. Most, however, will hesitate to give it in teaspoonful doses for fear of renal complications.

Dr. Billings has had gratifying success on the local symptoms with a solution of corrosive sublimate, one part to 1500 of water, used as a gargle, or with a syringe with a spray-nozzle, as was first suggested to him by Dr. Frank Johnson, of Chicago. The spray from a syringe may be injected with sufficient force against the pharyngeal walls and tonsils to dislodge the membrane and yet not wound or irritate the abraded surfaces.

Saccharine in Diabetes Mellitus.—This valuable addition to our materia medica renders the treatment of diabetes much easier. Dr. C. W. Purdy has given a clear statement of its antiseptic effects and indicated *how* it may be most conveniently used. Dr. Billings had used it in three cases of glycosuria dependent upon duodenal catarrh, and in one of diabetes mellitus. It fulfils the place of sugar as a sweetening agent, and also acts well as an antiseptic in preventing or relieving gaseous distension of the stomach and bowels.

Antipyrine.—Every day seems to add a new and valuable use of this remedy. Prof. Sée first used it hypodermically in a watery solution in all forms of neuralgia, rheumatism, and other painful affections. He advises friction over the injected area to relieve the disagreeable tension. Dr. R. Hirsch reports the use of the hypodermic injection of a fifty per cent. solution in twelve cases of rheumatism with marked success, relieving the pain and shortening the course of the disease. Dr. J. H. Etheridge, of Chicago, reported the hypodermic use of the drug in articular rheumatism. Several injections were made about the inflamed part with decided relief of pain.

Antifebrine.—Dr. Dumieville has used antifebrine as an anodyne in all neuralgias in over eighty cases with invariably good effect. Fifteen grains in twenty-four hours was the average dose. The effect is felt in from fifteen minutes to two hours. Several reports of cases have been made of dangerous collapse, with or without cyanosis, from the use of the drug. One death is reported of a child from antifebrine; the father of the child doubled the dose ordered by the physician, and death occurred from heart failure in twelve hours.

Sulphate of Sparteine.—This remedy has received more extended use during the last year, and many favorable notices of it have been written. Dr. J. Prior reports that it is indicated in all diseases of the heart where digitalis is contraindicated; where a quick effect is desired, and as an adjuvant to digitalis. He gives the remedy in doses of one-half to three grains, two to three times daily, and says the usually advised dose is too small.

In the discussion which followed this report,

Dr. C. Truesdale, of Rock Island, said that his experience and observations in the treatment of diphtheria were, that the main supports depended upon the character of the case he had to treat. One physician reports cases treated so and so with remarkable success; another, who adopts precisely the same course, loses a large percentage of his cases. He had used turpentine, bichloride of mercury, chloride of mercury, etc., and his experience had taught him that the best remedy was the old-fashioned treatment of the tincture of chloride of iron in large doses; and it was indeed remarkable to observe the large doses of that drug young children would tolerate.

Dr. Earle, of Chicago, said the author of the paper alluded to the cause of pneumonia. It had always appeared to him, especially in the treatment of diseases of children, that simply catching cold, or exposure to it, never could account for a very large number of cases reported. It appeared to him that there must be something beyond that—something in the earth or atmosphere to produce pneumonia in a large number of cases. He had come to the conclusion, although he had never conducted any scientific experiments to base such conclusions upon, that atmospheric influences of some indefinite nature played an important part in such cases, and it was on this account

that he always administered quinine in the treatment. He now regarded pneumonia as a very safe disease in a child, and much preferred a case of it to one of bronchitis involving the small tubes. If a child got a fair amount of quinine, and was well supported, it would get along extraordinarily well, and it was rare for him to lose a case that was fairly well nourished. With regard to diphtheria, he agreed with the last speaker that tincture of iron, etc., had given good results. He uses the tincture of iron, and chlorate of potash once in every four hours, but where it is desirable to make a good impression upon the pharynx such a dosage is not frequent enough; and recently he had given that mixture every two hours, and between it minute doses of bichloride. By carrying out this line of treatment his recoveries took place a little earlier than is usually the case.

Dr. J. W. Cowden, of Rock Island, said the treatment of diphtheria had deeply interested him. Jacobi recommends tincture of iron and chlorate of potassium. He, himself, gave it every fifteen minutes in teaspoonful doses—that is, he gave a child two years of age ten drop doses of tincture of iron. It will allay the pharyngeal inflammation and takes the place of a gargle. It was admirable when given in that way. In less frequent doses, or at a greater interval, it was disappointing. Another thing, was to support children by giving them milk in abundance. Children sometimes would also take an enormous amount of alcohol. He had a little child last winter that would take a teaspoonful of warm whiskey every half hour for forty-eight hours and would take nothing else with it.

Dr. Henry J. Reynolds, of Chicago, asked for some further light in regard to the physiological effects of antipyrine. He said it was an extremely powerful drug, and as useful as it was powerful, but thought it capable of doing a great deal of harm, in that in some cases it produced disorder of the kidneys, suppression of the urine, uræmic poisoning, etc.

Dr. T. W. McIlvaine, of Peoria, had used turpentine in the treatment of diphtheria in much larger doses than those mentioned by any of the previous speakers, and had had no toxic effects from the drug or unpleasant effect upon the secretions, especially of the bladder and kidneys. With reference to the use of bichloride of mercury, he had great confidence in it, used both internally and as a spray; he gives it in combination with lactic acid as a spray. The conditions under which antipyrine is administered should be more carefully studied. He had had patients in which it acted admirably under certain conditions, and again in the same patients the same dose had produced very unpleasant symptoms. He had in mind the case of a woman who had taken it several times with almost immediate relief, it being given in 7½ grain doses, repeated in one hour if the first dose was not sufficient. But on another occasion when the drug was made use of it brought on unpleasant symptoms, such as cyanosis, dizziness, trembling, purple lips, purple finger-nails—in short, rather alarming symptoms. Now, why it should so act at one time, and not at another, is a thing that should be carefully noted and studied.

Dr. J. S. Miller, of Peoria, remarked that in the treatment of diphtheria it seemed to him that, as Dr. Truesdale had said, we should adapt our remedies to meet the indications and emergencies of our cases. In anæmic patients, where children are not robust enough to tolerate active medication, the physician should be guarded in the administration of drugs. In the cases that had come under his observation he had demonstrated the efficacy of cold applications to the throat and angles of the jaws. In cases where there was high fever, and a high temperature, he would admit that there was no remedy which had given him as great satisfaction as the application of cold to the throat and neck.

He had had but little experience in the use of antipyrine. He had used it in cases of typhoid fever, and it produced almost fatal collapse. He had recently treated a case of malarial neuralgia with most excellent effect with antipyrine. Hypodermic injections failed to control a recurrence of the neuralgic attack, but a few doses of antipyrine controlled it immediately. That was the only case in which he had used antipyrine with good effect.

Dr. J. W. Morgan, of Port Byron, had used the biniodide of mercury in the treatment of diphtheria with gratifying results. It was far better than corrosive sublimate, from the fact that it was the most diffusible mercurial preparation we have.

Dr. Billings, in closing the discussion, said the paper was not intended to embrace the treatment of diphtheria, phthisis pulmonalis, or anything else, but was simply a *résumé* of the progress made and the new impetus the treatment of diphtheria had received by the use of the oil of turpentine.

Gynecology.

Dr. A. Reeves Jackson, of Chicago, chairman of the committee on gynecology, read a paper entitled:

"Hands Off; A Plea for Conservatism in Gynecology."

He said that during the past quarter of a century, and especially during the past ten years, no department of medicine has shown greater activity or made greater advancement than that which embraces the abdominal and pelvic surgery of woman. Many diseases which formerly baffled the utmost skill of the physician and surgeon, and doomed the patient to a life of pain and misery, or to certain death, are now treated with a highly satisfactory degree of success, and the lives that have been saved and made bearable by modern gynecological methods may be counted by the thousands. When we recall the fact that Sir Spencer Wells has performed 1,500 ovariotomies; that Lawson Tait has opened the abdominal cavity over 2,000 times for various purposes; that many other operators, at home and abroad, number their gynecological operations by hundreds upon hundreds, we cannot but be impressed by the great need for this work, and the incalculable benefit to suffering women that has resulted from it. No words of praise can adequately meet the deserts of these apostles of humanity. But, as an adverse result of the great success which has been achieved in this direction, there has arisen a class of ambitious imitators, who, actuated by more conceit than conscientiousness, more zeal than judgment, are rapidly bringing discredit upon the honest work of others in the estimation of many, who cannot, or, at least, do not distinguish between the real and the sham, the true and the false. These persons are apparently afflicted with an uncontrollable itching for rapidly acquired fame, and seem to think they can achieve what they desire by beginning where their masters left off. With them, gynecology no longer includes adequate effort for the cure of disease, and only signifies the art of cutting something out.

In one instance within his knowledge, when a spectator at an ovariotomy suggested a doubt as to the necessity for the mutilation, the operator audaciously pointed out that the ablated organs were already in a state of incipient cystic degeneration—the proof of the alleged fact consisting in the presence of Graeffian follicles in various stages of development.

When operations involving danger to life, such as laparotomy, are undertaken for the possible relief of vague nervous symptoms, hysteria, epilepsy, not clearly of ovarian origin, for insanity, or because there is nothing else to do, then such operations are improper, and should not be made. When a man is nervous, or irritable or insane, does anyone propose castration as a remedy? Would not such operation, although vastly less dangerous than the extirpation of the ovary, be regarded as malpractice? And when a corresponding operation is glibly proposed for a fretful, weak-backed, weak-minded, nervous woman, would not the opinion as to its necessity be greatly modified if the patient were a near relative—a mother, wife, sister, or daughter? And why? Because it is well-known that such operations are not always, not even frequently necessary, and that they sometimes kill, and do not by any means generally cure. If anyone finds himself in doubt as to the correctness of a conclusion in such cases, or as to his own honesty of purpose, let him take the case home to himself. If this were done there would be a smaller number of uterine appendages removed, a smaller number of hysterectomies performed. But, so long as the reputation of a gynecologist as such, is thought to depend upon the number of laparotomies he has done, rather than the number of patients he has cured and saved from mutilation, so long will the meetings of medical societies be enlivened by the presentation of platefuls of preserved ovaries and tubes.

The word "successful" in many cases in which laparotomy is done, means that the patient was not killed during the operation; that the reports are sometimes made so soon after an operation that the patient has had no time to die unless from shock, ether narcosis, or hemorrhage, and then no report seems necessary.

Once at a meeting of a medical society at which he was present, a fibroid tumor of the uterus was exhibited. The uterus and appendages had been removed by laparotomy a few hours before. He was informed the patient was "doing well." Inasmuch as there did not appear to have been symptoms sufficiently serious to warrant so dangerous an operation, he felt interested in learning the final result, which was that the patient continued to do well until she died six days later. The termination was not reported. An account of the case appeared subsequently in the published transactions of the society with this heading, "Successful Removal of a Fibroid Tumor of the Uterus."

This premature reporting of favorable cases (the others are frequently not reported at all), has the effect of misleading inexperienced persons who may feel tempted to repeat what seems to be so simple and beneficial.

Do you know, gentlemen, to what extent and for what purposes this indiscriminate laparotomy is proposed and performed? Let me cite a case or two that have come under my observation, all within less than a year: About nine months ago a gentlemen carried a woman in his arms into my office, and after placing her upon a lounge, said, abruptly, "Doctor, I want to know whether you can cure my wife without removing her ovaries?" The question was more easily asked than answered. I deferred giving an opinion until I had an opportunity of investigating the case. The woman was 30 years of age; she had been married eleven years, and had two children and one miscarriage, the latter having occurred three years before. She was a well-informed, well-nourished woman, of medium height, and had a wholesome visage. Menstruation was regular and painless; the functions of the bladder and rectum were normally performed, although there was a tendency to constipation; appetite fair usually, but capricious. Physical examination revealed a slightly congested lower segment of the uterus, the cervix being somewhat club shaped, owing to a slight laceration of the os uteri, on the inner side of which was a superficial erosion of no pathological importance. The ovaries and tubes could not be felt, and there was neither swelling nor tenderness in their neighborhood. The woman was fretful, irritable and lazy. She had been under medical treatment for various ailments (which she probably did not have), during the last three or four years, and had been the latter six months under the care of a gynecologist in Chicago, who had used the customary hot douches, glycerine tampons, massage, etc., without perceptible result. When the impatient husband asked whether anything more or anything better could be done, he was told that the only thing that offered relief was the removal of the ovaries. There was no pelvic disease present, and there was no further pelvic treatment. The patient left the city in a few weeks for her home.

About two months ago Dr. Jackson learned that she was pregnant, and still later, that she was doing well and was able and willing to do all kinds of light housework, and to take moderately long walks.

Again, a young woman, 19 years of age, had been suffering occasionally during several years from irritable bladder. She had been treated by a number of physicians with sometimes temporary benefit. Being finally referred to a gynecological semi-specialist, he informed her that inasmuch as so many remedies had failed to cure her, he would advise the removal of the ovaries. She still has them.

In a third case, the patient was 22 years old; menstruation commenced at 12, but had always been scanty and irregular, appearing at intervals of from six weeks to as many months. Her appetite was poor, complexion sallow, and her face affected with acne. She was advised to have her ovaries and tubes removed —with what object she could not imagine, unless it was to transfer them to a bottle or plate. May 1, her physician in reply to a letter wrote Dr. Jackson as follows: "The soft rubber stem was retained for three months, which established her menstruation in much better condition than previous to its introduction— that is as regards the quantity of the flow. I find she is in very good health as compared with what she was last year."

Think of it! Women advised to have important organs removed, the mutilation involving dangerous operations, for the cure of a nervous affection of the bladder, for scanty menstruation dependent upon feeble general health, and for laziness! Does not all this justify a remark recently made by Thomas Keith, that "in abdominal surgery responsibility seems to have become old-fashioned and gone out of date."

Dr. Horatio R. Bigelow, speaking of the dangerous tendency to operative measures, said: "Who can begin to enumerate the number of cases in which the abdomen has been opened for supposed ovarian diseases, when not a trace of anything pathological was discoverable? Who will write the history of the cases in which perfectly healthy ovaries have been removed as an offending cause without the least improvement in the general condition of the patient? A human being mutilated, deprived of her distinctive characteristics, and rendered miserable! A human life poised between earth and heaven to gratify a bad diagnosis, faulty pathology, or the personal conceit of an irresponsible practitioner! A human life sacrificed to ambition upon the operating table! Do you wonder, can you wonder, in the face of the grinning, horrid, damning facts, some of which are on record, and a host of which hide their ghastliness in dark places, that there should go out throughout the land a cry for conservatism?"

The evils to which he had called attention were great. Dr. Jackson feared they were growing worse. A woman has an inalienable right to all the organs with which she has been endowed. She should only be deprived of any of them when it is clear that through disease or faulty function, otherwise incurable, her health is seriously impaired or destroyed, or her life imperilled, and only then when deprivation reasonably promises relief. To those who from selfish, reckless, or other improper motives, would remove from a woman any of her peculiar organs, he would say, in the name of womanhood, in the name of common honesty, in the name of humanity, "hands off."

Dr. J. M. Cullimore, of Jacksonville, read a paper on the

Menopause.

The most important and frequent pathological conditions incident to the menopause are first, the premature menopause; second, neuroses; third, hemorrhages. Under the first head he included those cases which, at about the usual age or earlier, the periods which have hitherto been regular cease for a time. The condition usually comes on in direct consequence of physical or mental shock, some general disease, some genital affection, mechanical violence or blows, sudden bereavement, tuberculosis, typhus or typhoid fever, cholera, pyæmia, inflammation of the ovaries, and difficult labors.

Under the second head the uterus, ovaries, Fallopian tubes, the clitoris and labia, the bladder, urethra, rectum and perineum joined in producing both local and reflex nervous disturbances at the period of the climacteric.

The third class includes those hemorrhages due to cancerous degeneration, to softening of the uterine tissues, and particularly of the mucous membrane.

Dr. O. B. Will, of Peoria, in opening the discussion, said that so far as he was personally concerned he could approve every sentiment expressed in Dr. Jackson's able paper. He could not agree with Dr. Cullimore, however, that the menopause or change of life was pathological. It is a physiological change, and as such under circumstances of good general health will terminate favorably in each instance. It is only where other well formed disease conditions are present that we have the disease manifestations. He would treat that class of cases as he would a disease of a similar kind, whether it was at the menopause or not. There is a morbid condition present in such instances that must be reached, and is not dependent upon simply the matter of change of life.

Dr. Earle, of Chicago, said he wanted to say a word or two in commendation of the paper. It was timely and exceedingly appropriate, and he thought it absolutely necessary that some one should read just exactly such a paper as Dr. Jackson's, with the hope of eradicating or removing the craze that had seized a large number of physicians for operating.

Dr. C. Truesdale, of Rock Island, remarked that he may have misunderstood Dr. Jackson in the beginning of his paper as to whether he commended the work of Lawson Tait and Sir Spencer Wells. If he understood the matter aright, a laparotomy that had for its object the removal of the uterine appendages was an operation which was being greatly abused, and that if there was any man responsible for it, it was Lawson Tait, for he had operated in this way oftener than any other man in the civilized world. He would admit that Tait had been successful in his operations if the reports of percentages of deaths could be relied upon.

Dr. Jackson, in closing the discussion, said that his allusion to the work of Sir Spencer Wells and Mr. Tait was only intended to show that, whether they were always right or wrong, there is a foundation for the great amount of work they had done and are doing, as he considered them honest, and highly commended them in such a line of work; but he had reference more particularly to the fact that perhaps hundreds of lives had been sacrificed through the indiscriminate use of the operation by inexperienced, ambitious imitators, whose desire was to open the abdomen and cut something out.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN PRACTICE OF MEDICINE.

Stated Meeting, May 15, 1888.

R. C. M. Page, M. D., in the chair.

The Therapeutic Value of the Saratoga Waters.

Dr. T. Herring Burchard, the author of the paper, gave our very limited definite information regarding their therapeutic value as an excuse for calling attention to waters which had for so many years been used by the American public. The danger of partaking of the waters without medical guidance was shown in the fact that he knew of two persons in whom their use in excessive quantity had caused death; while in others it had given rise to gastric, pulmonary, bronchial and renal affections. Rules for their medicinal use were formulated on clinical

observation and on their supposed action, according to the mineral ingredients which they contained.

In all of the twenty-eight or more springs, the water was charged with carbonic acid gas, and usually to a much greater degree than any of the waters of Europe, which rendered it more tasteful. The Congress was mildly cathartic and tonic, while the Hathorn was more strongly cathartic, and for a few days acted very satisfactorily, but if continued it not infrequently caused rectal or renal irritation. The use of the Congress was not followed by subsequent obstinate constipation. The Vichy was less alkaline than the European Vichy, but it contained a larger percentage of carbonic acid gas. On the other hand, the Columbian and the Hamilton Springs contained more iron than those of Europe, there being in each pint of the Columbian Springs 698-1000 of a grain, and in the Hamilton 578-1000 of a grain. Dr. Burchard thought the benefit produced by iron in anæmia, chlorosis, etc., was greater when taken in the spring waters than when administered in the form of a tincture or otherwise. There were two sulphur springs, for which decided advantage was claimed in the treatment of rheumatism and catarrh, although his own experience with them had been negative. After pointing out the general characteristics of the waters, Dr. Burchard considered the probable effect which any given water would have upon any given disease; also the personal peculiarities of the patient; the very important question of exercise and regimen during the taking of the waters, and how the waters could be best given to meet these requirements.

It was best to place the patient on small, regular doses, increasing according to the therapeutic effects observed. The diet, as a rule, should be simple and non-stimulating; the heavy albuminoids should be sparingly used. In cases of chronic dyspepsia there should be the utmost care taken against the occurrence of flatulence and colic. The patient should not exercise to fatigue.

The diseases in which benefit was to be expected were not acute, but chronic, and in his experience were the following: Dyspepsia dependent on gastric or intestinal catarrh; dyspepsia from gastric or intestinal atony or constipation; chronic constipation; hepatic derangement; lithiasis and oxaluria; biliary concretions with a history of hepatic colic; chronic Bright's disease with secondary complications, especially chronic anæmia, gastric catarrh, etc.; general debility and anæmia; rheumatism and gout; and, strange to say, he had seen much benefit in some cases of diabetes.

Dr. Burchard thought that if the use of the waters at Saratoga was under proper guidance many people would be saved the expense and time of going to European springs, which were used under the advice of medical experts. The great variety of the waters at Saratoga would spare patients the trouble of going from one spring to another, which was rendered necessary on the Continent.

The paper elicited some general remarks from Dr. G. B. Fowler, who thought people usually did not drink sufficient fluids, considering that the human body was largely composed of water; from Dr. Doremus, who thought that the effect of many waters now on the market was simply that of pure water or of salt waters impregnated with carbonic acid gas, and was glad to see the medical profession taking cognizance of the advantage of American mineral waters; from Dr. L. D. Bulkley, who had obtained benefit from the sulphur springs of Saratoga, and who thought the reason why patients did not remain permanently benefited after going to the springs was, that on returning to their homes they returned also to their former bad habits. He thought harm might come from the custom here of taking the mineral waters cold, whereas in Europe they are used warm. He had obtained much benefit by administering simple hot water before meals, having patients avoid iced water with meals.

Dr. W. B. Wood then read a paper on

Recent Clinical Results with the Pneumatic Cabinet.

The pneumatic cabinet is the instrument invented by Dr. Williams, of Brooklyn, for the treatment of chest affections, and consisting essentially of a chamber from which the air could be more or less completely exhausted, forming a partial vacuum around the patient's body, while he inhaled air through a tube from without. The inhaled air could be medicated if desired.

Dr. Wood's paper was supplementary to one which he had read within a year, and in it he narrated about eight cases recently treated, and stated that by this method pleuritic adhesions, and in a general way, pleurisy could be positively cured; and that inasmuch as the evidence which he offered in addition to that commonly furnished by autopsies went to show that pleurisy always preceded phthisis, he thought the latter disease could, if taken in time, also be prevented.

The experience of Drs. D. R. Brown, Sidney Fox, Williams and De Watteville,

who had employed the pneumatic cabinet, was confirmatory of that of the reader of the paper. Dr. Williams had always sought to prevent physicians from drawing irrational conclusions regarding the action of the cabinet. He had never asserted that it would cure phthisis. He had impressed its value in warding off the disease, and the improvement which had resulted in developed cases.

Dr. De Jager did not wish to question the clinical results of the advocates of the pneumatic cabinet, but he could not understand wherein its action differed from Waldenberg's apparatus for the inhalation of condensed air, and he would like, inasmuch as the cabinet was too expensive for physicians generally to purchase, to have a committee appointed to report on its mechanical or other action.

Dr. Beverly Robinson gave expression to the same desire, and was decidedly skeptical as to the cure of pleurisy and old pleuritical adhesions in eight or nine days.

Dr. A. S. Hunter had found much benefit from the chest expansion and lung capacity developed by the pneumatic cabinet in women who had been chronic complainers, and had received all sorts of treatment, such as repair of the lacerated cervix and of the perineum, etc., at the hands of various physicians, and whose condition had in no wise thereby been permanently improved.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

THIRTY-NINTH ANNUAL SESSION, AT PHILADELPHIA, JUNE 5, 6, 7, 8, 1888.

First Day, Tuesday, June 5.

The Society was called to order by the President, Dr. R. J. Levis, of Philadelphia.

Prayer was then offered by Right Rev. O. W. Whitaker, D. D., Bishop of Eastern Pennsylvania; and this was followed by the presentation of register of delegates by Dr. W. B. Atkinson, Permanent Secretary.

The address of welcome was then delivered by Dr. John H. Packard, Chairman of Committee of Arrangements.

Dr. Packard briefly sketched the origin of the society and its succeeding history, the good it had accomplished and would accomplish, and in the name of the Philadelphia members extended to the visiting doctors a hearty and sincere greeting.

The medical officers of the army and navy of the United States who are resident, or at present in Philadelphia, were invited to take seats as guests of the Society.

Dr. DeWolf, delegate from the Medico-Chirurgical Faculty of Maryland, was presented.

Report of Delegates to the American Medical Association was read by Dr. Anderson. The Treasurer, Dr. O. H. Allis, then read his report.

The report of Dr. Allis, the Treasurer of the Society, showed that during the year there has been $3,974.54 in the treasury, $2,794 of which was the balance from the preceding year. The expenditures were $2,338.16, leaving a balance of $1,636.38. The following auditing committee was appointed: Dr. Pollock, of Pittsburg; Dr. Green, of Easton, and Dr. Willard, of Philadelphia.

The Committee on Publication then reported, through its Chairman, Dr. Wm. H. Parish, that 2,250 copies of the transactions of the Society for 1887 had been distributed at a cost of $764.59. Last year only 2,000 copies were published, and these cost the Society $1,618.88. An interesting feature of the report referred to the financial relations of the County Societies to the State Society. It appears that at the beginning of the year just ended, only 17 out of 50 County Societies had paid their full share of the expenses of the State Society. The committee believes that with careful business management, the annual dues *per capita* can be reduced from $1.50 to $1.00—perhaps, seventy-five cents.

The following amendment to the constitution was adopted:

"That the censors of the appropriate district, or districts, shall have power to determine whether a resident of one county shall be entitled to become a member of an adjacent County Society which may be more convenient for him to attend."

Also, the following amendments to the By-Laws:

"Sec. 5. The Committee on Pharmacy shall consist of five members, to be appointed annually by the President, whose duty it shall be to consider all matters pertaining to Pharmacy, and who shall be empowered to represent this Society in conference with a similar committee to be appointed by the Pennsylvania Pharmaceutical Association. They shall report annually the result of their joint labors."

And a section, not numbered:

"There shall annually be constituted as the first item of business at the afternoon session of the first day, a Nominating Committee to

consist of one member from each county, named by a majority vote of the delegation from that county, who shall report as the first item of business in the afternoon session of the second day a list of candidates for officers and necessary committees."

The Committee on Medical Education made a report through its Chairman, Dr. Jackson, and offered the following resolutions:

Resolved, That a committee of five be appointed by the President to secure the coöperation of county medical societies and individuals interested in the subject to urge upon the State Legislature the enactment of a law essentially identical with that proposed by this society, and favorably reported to the House of Representatives at the last session of the Legislature.

Resolved, That the sum of $100.00, or so much thereof as may be required, is hereby appropriated to meet the expenses of that committee.

Dr. Finley, of Altoona, objected to medical legislation, and quoted instances to show that such legislation had rarely been felicitous in its results. "If the Legislature passes the proposed act," he said, amid laughter, "the Board of Examiners would be composed of charlatans, bummers, ward politicians, homœopaths and other so-called members of the medical profession."

The consideration of the resolutions was postponed until after the reading of two papers on the programme on this subject.

New Committee on Clinical Research.

Dr. J. Madison Taylor, of Philadelphia, proposed that in the place of the present Committee on the Collective Investigation of Disease there be constituted a Committee on Clinical Research, consisting of 15 members, a Chairman, Secretary, Assistant Secretary, Physician, Surgeon, Obstetrician and Pathologist, whose duties shall be to coöperate with observers in placing on record clinical observations for the special purpose of increasing the scope and interest of papers read before the annual meeting of the State Medical Society. It shall act as a medium of intercommunication between members of the State Society for the collection of notes, specimens and the like, as it is hoped by such aggregation to increase and utilize the value of material obtained, and encourage and aid in research those to whom competent libraries are inaccessible.

The resolution was endorsed by Dr. Tyson, chairman of the Committee on Collective Investigation, Dr. Dercum and others, and was adopted.

Management of Hospitals for Insane.

Dr. Hiram Corson presented a preamble reciting the disadvantages of the system under which the Superintendents of the State Hospitals for the Insane at Harrisburg, Warren and Danville are charged with the business management of the hospital, as well as the medical care of the patients, and offered the following resolution:

Resolved, That a committee of seven be appointed by the President of this Society to memorialize the Legislature for such change in the law governing the three hospitals named, as will confer on the Boards of Trustees full and exclusive power of management, and make it incumbent on these Boards to provide that medical chiefs, male and female, and their assistants shall perform such duties only as pertain to their offices as physician to the insane.

A prolonged and animated discussion followed.

Dr. S. S. Shultz, Superintendent of the Hospital at Danville, spoke at length on the opposite side of the question, upholding the plan of having the administration of the institution concentrated under one head, as it is in the three institutions named by Dr. Corson.

Dr. W. T. Bishop, of Harrisburg, opposed the preamble and resolution, and moved that they be returned to Dr. Corson. He said that the superintendents were responsible to the Trustees and to the Governor of the State, and it was therefore useless to charge them with dereliction and then ask the Legislature to change the conduct of affairs.

Dr. E. A. Wood, of Pittsburg, spoke warmly against any such action, which, he said, would be an insult to one who had been a lifelong philanthropist.

Dr. John Curwen, Superintendent of the Hospital at Warren, and Dr. John C. Gerhard, Superintendent of the Hospital at Harrisburg, also opposed the resolution.

Dr. J. Z. Gerhard, of the Harrisburg Hospital, emphatically denied any dereliction of any duty.

Dr. Corson was then given ten minutes to further explain his views. He said that he had no self-interest in the matter, but thought that it was a question of the greatest importance to the people of the State. He said that the idea was to put the Danville, Harrisburg and Warren institutions on the same plan as that at Norristown, which was managed in the way he proposed. He said there was not a better managed institution in the civilized world. A motion to adjourn in the midst of the discussion had been made and lost, and Dr. Seltzer had unsuccessfully moved that the

resolution be laid on the table. When Dr. Corson had ceased speaking the motion was passed and the resolution was tabled.

At the afternoon session, Dr. Traill Green, of Easton, delivered the

Address on Hygiene,

In which he emphasized the importance of proper ventilation, cleansing of the skin, and drainage. It is the duty of physicians, he said, to point out to their patients violations of the laws of health. Dr. Green devoted much attention to the facts of the general absence of great suffering in the hour of death, the almost utter impossibility of such a thing as premature burial, and the common error, one unsupported by facts or science, that the bodies of the dead are eaten up by worms. The truth concerning these facts the physician should always present to his patients, and prevent much needless terror among them.

Dr. Benjamin K. Lee, spoke of the danger of keeping vegetables in cellars, unless the latter are well ventilated.

Dr. Edward R. Mayer, of Wilkes Barre, delivered the

Address on Medicine.

He sharply criticised the so-called Christian Science, and argued that internal medication had its triumphs no less notable than the external operations of surgery, which could be seen and known of all men, and quoted numerous examples to sustain his argument.

The Chemical Factor in Disease,

was the subject of a paper by Dr. Hugh Hamilton, of Harrisburg.

Dr. William Pepper, of the University of Pennsylvania, presented, but did not read, a paper entitled

A Contribution to the Clinical Study of Albuminuria,

In which he stated that of 239 supposed cases in his private practice during the past eight months examined by his assistant, Dr. J. P. Crozier Griffith, nearly 143 were found to be cases of albuminuria. He concluded that the gravity of the case as indicated by the presence of albumin was frequently much exaggerated.

Dr. Frank Woodbury presented

A Note on Effervescent Salts as Vehicles for the Administration of Certain Medicinal Agents.

He traced the popularity of many drinks to their effervescent quality, and their consequent useful medicinal value in the direction indicated. He thought that if some one could produce a solution of hops without alcohol it would be a great contribution to the solving of the temperance question. Carbonic acid water affords a useful agent for the administration of nauseous medicines, or such as it is desirable to dilute freely.

After the adjournment of the session, an informal reception was given to the delegates at the University of Pennsylvania. The delegates were met in the dental building by the Provost and several of the professors, and, after they had visited the veterinary, biological and other departments, supper was served in one of the rooms.

A reception was given in the evening at the Academy of Fine Arts by the President, Dr. Richard J. Levis.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 17, 1888.

The President, A. Jacobi, M.D., in the chair.

A New Lectureship.

The Trustees of the Academy accepted a donation of five thousand dollars from the estate of the late Dr. Wesley M. Carpenter, with which to found a lectureship to be known as the Carpenter Lectureship.

Dr. B. F. Westbrook, of Brooklyn, read the principal paper of the evening, on

Pleurisy as a Predisposing Cause of Phthisis Pulmonalis.

Since it has been proven almost beyond doubt that the bacillus tuberculosis is the exciting cause of phthisis pulmonalis we should inquire whether certain local conditions will not so affect the lung tissues as to render them specially liable to the invasion of this micro-organism. He thought it must be admitted that something in the nature of a predisposing cause must exist in susceptible individuals. There had been much discussion with regard to the relationship which different diseases bore to each other. With regard to that relationship as it concerned phthisis and pleurisy he laid down the following classification, and gave illustrative examples:

First.—Cases of pleurisy antedating the outbreak of phthisis pulmonalis. In these cases a pleurisy with effusion occurs in a person apparently in good health, and is immediately followed by evidences of pulmonary tuberculosis, which usually runs a rapid course to a fatal termination. In these cases the pleurisy is undoubtedly tubercular in origin, and forms but a part of a general disease, and its discussion is not germane to the subject.

Second.—This class includes those instances in which a sero-fibrinous pleurisy is followed by a slow development of chronic interstitial

pneumonia, the fibroid phthisis of Sir Andrew Clark.

Third.—Cases in which an acute or subacute attack of sero-fibrinous pleurisy terminating in complete recovery is followed after some months by the development of tuberculosis at one or both apices, usually observed in persons who are constitutionally weak or whose health has been injured by debilitating influences. Cases of this kind are not very numerous.

Fourth.—This class includes cases occurring usually in those of middle age or in the decline of life, in which a sero-fibrinous pleurisy has become chronic, and in which on account of the density of the false membrane covering the lung and the diminished pliability of the parietes of the chest, absorption has not occurred. They are typical cases of chronic sero-fibrinous pleurisy, which have either failed to be recognized or have been left to the uncertainties of nature. It is a fact that some of them finally develop tuberculosis either in the lungs alone or the general disseminated form.

Fifth.—Cases of empyema, the appearance of which antedates the appearance of tuberculosis. This class is introduced simply to make the list complete.

Dr. Westbrook's conclusions were: That sero-fibrinous pleurisies apparently simple in origin and terminating in complete recovery so far as the local manifestations are concerned, may be followed after the lapse of a few months by the development of phthisis pulmonalis; that in all probability the pleurisy in these cases acts as a predisposing cause of the tuberculosis; that primary sero-fibrinous pleurisy may result in fibroid phthisis with the subsequent occurrence of tuberculosis pulmonalis; that fluid effusions remaining in the chest for a long time may finally so interfere with the nutrition of the lungs or of the body at large as to render it liable to tubercular inflammation either local or general. The rational deduction from these facts is that no case of pleurisy should be neglected. The patient should not be lost sight of for sometime after his health has apparently been completely restored, and under judicious gymnastics there had been much chest expansion and improvement of the general condition.

Dr. Williams, of Brooklyn, read a brief paper on

Some of the Determining Causes of Pleural Exudates,

and spoke of pleurisy being either sthenic or asthenic; of an hereditary or constitutional condition, in which there was demonstrated richness of cell proliferation in inflammatory products, with proneness to organization. The subject of such a tendency was liable when pleurisy occurred to have the surfaces blanketed with a pseudo-membrane in seeming disproportion to the exciting cause. In a second class of cases there was early pulmonary immobility, regional or entire, not due to pleural disease, but antedating this. In a third class of cases there was constitutional infection by the bacillus tuberculosis. Such were some of the conditions favoring pleural exudates.

Dr. J. Blake White in a brief paper gave expression to the view that pleurisy not only frequently occurred in pulmonary tuberculosis, but that it might give rise to the lung affection in persons who had previously been healthy. We often see, he said, neglected cases of pleuritic adhesions in patients suffering with a hacking cough and progressive emaciation, their condition having been allowed to progress until it has become irreparable. The question of preventing as well as curing phthisis depended, he thought, more upon increase of lung capacity, especially about the apices where activity is naturally least, than on purity of air or bacilli, though he would welcome the former for its therapeutic value and would be pleased to know of the absence of the latter as evidence of there being no suppurative inflammation. Regular systematic lung exercises in children, with judicious diet, would do much to prevent phthisical tendencies and chest deformity as life advanced. He was not prepared to accept the teaching that tuberculosis was due to the bacillus tuberculosis; he thought the bacillus was the result of the phthisical process.

Dr. W. B. Wood read a brief paper on the treatment of

Predisposition to Phthisis in Children who had had Pleurisy.

He thought that in all cases before phthisis actually developed there was a stage at which there must have existed predisposition. The manifestation of predisposition to phthisis is diminished breathing power or respiratory function. There are two great causes of deficient respiratory function in children, viz., impeded nasal respiration and thickened and immobile pleura at the base of the lung, and any treatment which would successfully overcome these conditions constituting predisposition would, in the vast majority of cases, effectually prevent the development of phthisis. It would be necessary to secure free breathing through the nasal

passages by the proper treatment directed to them, and to institute a system of lung gymnastics.

Dr. E. T. Bruen, of Philadelphia, opened the general discussion, and said that during the past few years considerable attention had been devoted to the question whether or not the etiological conditions of phthisis might not have a bearing upon the development of pleural processes. He added two cases to the general testimony going to show that the pleurisy might be of a tubercular origin before the occurrence of tuberculosis of the lungs. He thought it was no argument against the view that the pleurisy was of a tubercular origin that the disease was not infrequently entirely recovered from, for we saw tuberculosis in other portions of the body, as in the peritoneum, disappear completely. He would, therefore, lay more stress than Dr. Westbrook had done on the tubercular character of the cases under consideration. He thought physicians failed to recognize as they should the importance of general exercise in chest diseases, and devoted too much attention to the development of respiratory capacity. Neither should be neglected.

Dr. F. C. Shattuck, of Boston, dwelt upon the question of tubercular origin of pleurisy, and said that about three years ago he added a note to Strümpell's Text-book of Medicine, in which he gave expression to the view that in America facts did not bear out Strümpell's opinion that pleurisy due to cold was extremely rare, for here many patients absolutely recovered from the disease. Since that time he was becoming more impressed with the frequency of a tubercular origin of pleurisy. We had not generally freed ourselves of the impression that tuberculosis meant pulmonary tuberculosis, and that the disease was almost inevitably fatal. Tubercular inflammation might be localized in different parts of the body, among others in the pleura, and be entirely recovered from, or it might go on to affect other portions, as the lungs. As to pulmonary gymnastics, the best form was mountain climbing.

Dr. E. G. Janeway would be disposed to regard tubercular phthisis occurring within a few months or even a year after an apparently simple sero-fibrinous pleurisy, which had disappeared, as a result of a tubercular disease, and not of a simple inflammation leading to tuberculosis pulmonalis. It was common in making autopsies on cases presumably of simple pleurisy to find evidence of a tubercular condition. The search for the bacillus tuberculosis was a difficult one, and failure to find it was not proof that the process was not tubercular.

Speaking of failure of aspiration to prevent re-collection of the fluid in the pleural cavity, he said that often the fluid would become absorbed by limiting the fluids taken by the patient to one-third or one-half of the amount of urine passed, and giving him sufficient of the iodide of potassium and chloride of sodium to make the blood thirsty for liquids.

Dr. Westbrook, in closing the discussion, said that he had treated the subject from the clinical rather than the pathological standpoint. He did not think the evidence was at all sufficient to show that all cases of pleurisy were of tubercular or infectious origin. He did not see why the pleura of all the tissues of the body was incapable of taking on inflammation except that of an infectious nature.

The Constitution of the Society was revised so as to take in as active members physicians in any part of the State of New York, and extending non-resident membership to those residing without the State.

Periscope.

Athetosis in a Girl Twenty Months Old.

At the meeting of the Société Médicale des Hôpitaux, of Paris, April 13, 1888, M. Comby stated that he had then under observation a little girl twenty months old, who had been suffering since the eighth month of her life with hemi-athetosis of the right side. This child, though nourished at the breast, had nevertheless received too much solid food. She is now subject to attacks of vomiting and diarrhœa; she is slightly rachitic. The father is tuberculous; the mother healthy, but she gave birth to a child which died of meningitis when five years old.

The onset of the athetosis was marked by violent convulsions which lasted several days. At present, he says, in the standing position she supports herself principally upon the left limb; she incessantly turns the right foot up and moves the toes. The hand upon the same side is likewise extended and flexed, and moved from side to side, as is characteristic of athetosis. The general sensibility is undisturbed; there is nothing abnormal about the eyes, and no muscular atrophy. M. Comby remarks that athetosis is extremely rare in a children's clinic; in 30,000 consultations given in five years, he has never observed but one.—*Bulletin Médical*, April 15, 1888.

Extirpation of the Kidney.

At a meeting of the Berlin Medical Society, March 7, 1888, Dr. E. Küster presented a patient whose left kidney he had excised for tuberculous disease. The patient was a man, 38 years old, of healthy parentage, though his younger brother is at present suffering from disease of the lung. In 1886 he was attacked with fever, the source of which was not recognized; he became very much emaciated. In April of the past year, a tumor of the left kidney was discovered, for which nephrotomy was done, and the kidney drained. But suppuration did not subside, so that a second incision was made in front, and the kidney drained clear through. This second incision was carried through the peritoneum without untoward result.

When the patient applied to Küster for treatment in October of last year, he was extremely emaciated. There were two fistulæ in the neighborhood of the kidney which gave vent to stinking pus. The author then supposed that the trouble was a simple pyonephrosis, the more so, as the urine which came only from the right kidney presented no abnormal constituents. But on uniting both fistulæ by an incision, he explored the kidney with his finger, and found that there were a number of holes in it, and from these he expressed with his finger caseous yellow pus. He at once thought the disease tuberculous, and as the other kidney was sound he extirpated the left kidney by horizontal lumbar incision. Recovery was rapid. The patient has two fistulæ, which are scarcely discernable, and has gained forty pounds in weight in two months.—*Deutsche med. Wochenschrift*, March 15, 1888.

Intraparenchymatous Injections of Ozone Water for Cancer.

Dr. Joseph Schmidt, of Aschaffenburg, has employed in two cases intraparenchymatous injections of ozone water for cancer, and has obtained such surprising results that he seems induced to submit this method of treatment to a further trial. According to the *Münchener med. Wochenschrift*, No. 16, 1888, the method consists in the injection of ozone water in the strength of one to three grains to a quart of water. The injections were made with a Pravaz's syringe. The number of injections varied, according to the size of the affected area, from one to ten or more a day. They were made into the mass of the cancer itself, as well as into the healthy tissue bordering upon it, and even into the swollen and suspicious glands. The pain when the injections are made with a rather dilute solution is not very marked, and disappears completely after several minutes or half an hour. Frequent local symptoms, especially when the injections are made with rather strong solutions, are, after a short time, moderate œdema, and slight redness and tenderness to the touch; these symptoms disappear in a few hours when the weaker solutions are used; but when the stronger solutions are used, they last for several days. During the progress of this treatment the cancerous ulcers became cleaner, smaller, and cicatrize. The cancerous nodules grew smaller, and became gradually very hard, so that the introduction of the needle was often difficult, and was accompanied with a grating sound; in such places but a few drops could be injected with difficulty. After treatment had been continued some time the parts, which at the beginning were swollen became peculiarly dense, tense with œdema, of a bluish-red color, and tender to the touch, as well as painful. When such parts were cut, under the skin, which appeared normal, was seen an œdematous, cellular tissue, and under this a thick, dense, callous mass. The microscope revealed but very few nests of cancer cells. When this treatment was continued longer, the swelling receded, and a connective tissue shrinkage occurred. Bad consequences from the injections were never noticed.—*Wiener med. Presse*, May 6, 1888.

Erysipelas and Puerperal Fever.

At the meeting of the Academy of Medicine of Paris, March 13, 1888, M. Doyen said that he had investigated the reports which connect erysipelas and puerperal fever. From a comparison of clinical and experimental facts he draws the following conclusions:

1. The puerperal streptococcus, which is the microbe characteristic of puerperal fever, nearly always gives rabbits erysipelas and a small abscess; in a woman it sometimes produces erysipelas, cellulitis, or purulent pleurisy. 2. The streptococcus of erysipelas nearly always gives rabbits erysipelas, and at times even cellulitis or peritonitis to man. 3. The streptococcus of pus at times gives erysipelas to rabbits. The three streptococci, which are identical in cultures, appear to be one, of which the manifestations may vary. Doyen has never seen the streptococcus in his studies of the microbes of the vagina, and he believes that this microbe when it is met with in the cavity of the uterus has been imported there directly by the hands or the instruments of the operator.—*Revue Médicale*, March, 1888.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D., Editor.

Original Contributions will be paid for when published; or 200 reprints will be furnished in place of payment, if a request is sent with the manuscript.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - - 1.25
Reporter and Pocket Record, - - - 6.00
Reporter, Compendium and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

IMMEDIATE PERINEORRHAPHY.

To those who are accustomed to do immediate perineorrhaphy for rupture of the perineum, it seems strange that anyone should oppose the performance of this operation. Yet there are many who not only do not employ this plan of treatment in their practice, but deny its propriety, and seek to prove that it is either unnecessary or harmful. Fordyce Barker is among the most prominent of those who oppose the operation in this country. Charpentier expresses an opinion very prevalent in France, when he advises operation only after three months' waiting, in lacerations extending through the sphincter ani, and states that less extensive tears heal spontaneously. Other recognized authorities are opposed to the immediate operation. It is still not uncommon to hear physicians say that they never have rupture of the perineum in their practice, and this, in spite of the fact that such men as Schröder, Olshausen, and Winckel, report lacerations in more than twenty per cent. of primiparæ and five per cent. of multiparæ. These practitioners fail to see that their statement is an admission that either they do not look for lacerations, or else that they are not able to recognize one when they see it.

As objections to immediate perineorrhaphy, it has been urged that union will occur spontaneously in incomplete lacerations, if the parts be kept clean and the knees tied together; that the wound is contused and hence is not apt to heal after suturing; that the shock from the operation done immediately after labor might cause flooding; that sepsis is favored; and, finally, that if nature fails to bring about a cure, a result as good or better can be gotten by an operation done some weeks after labor, as by immediate suture. We are in accord with those who believe that these statements and objections are not sound. No one will deny that a laceration extending only through the skin or mucous membrane and the underlying connective-tissue will unite spontaneously, but at the same time it will unite more rapidly and with the formation of less scar tissue, if permanent coaptation of the sides of the wound is secured by the use of sutures. But the suture, in this class of cases, is relatively of little importance, since no special inconvenience would result if union failed to occur. Nothing is better known than that tying the knees together has no influence one way or the other in securing union in laceration of the perineum. Anyone can demonstrate that the knees can be separated to the fullest extent without putting the perineum on the stretch. The daily attendance of women with lacerated perineum at dispensaries, and the host that consult gynecologists for the same condition, sufficiently disproves the statement that spontaneous cure is the rule after this accident. Indeed, analogy alone would teach the contrary in all cases where the tear is sufficiently deep to involve the muscles and fasciæ making up the perineal structure. The rule is that muscles, when cut across, retract, forming a hiatus between their several ends; and the muscles which centre in the perineum, when torn, retract and form a gaping wound, which cannot unite spontaneously from the very nature of the anatomical conditions present. The suture is necessary to hold the torn tissues in apposition and to secure union.

The objection that the contused nature of the wound is apt to interfere with primary union is only partly true. The great majority of lacerations are but slightly, if at all, contused, and union is secured in about ninety per cent. of cases. Contusion of the perineum is usually the result of neglect in the management of the second stage of labor by the physician, allowing a tedious second stage to continue till the impaction of the presenting part in the inferior strait, with tumefaction of the maternal tissues, from obstruction to the circulation, occurs, or to bungling use of the forceps, or to unjustifiable traction efforts. That it is occasionally advisable to dispense with the suture of lacerations of the perineum, owing to the contused condition of the tissues, is usually simply a demonstration of the fact that the second stage of labor is not always properly conducted. The fear of special post-partum hemorrhage is groundless, as experience has shown. Were the wound already infected before it was closed, of course septic absorption would be favored; but with the careful use of antiseptic precautions, this is scarcely possible; and the accurate coaptation secured by carefully performed immediate perineorrhaphy is a very certain preventive of subsequent infection. The fact that immediate closure of perineal rents is classed, by hospital accoucheurs, among the steps of antiseptic midwifery is certainly a sufficient refutation of the statement that sepsis is thereby favored. It seems to us that the teaching that the perineum can be as well restored by secondary, as by primary perineorrhaphy, is most pernicious. Doubtless this is true so far as superficial tears are concerned, but in the majority of cases these are of no importance whatever, except in that they may afford an entrance to septic infection, during the puerperium. But the case is entirely different in tears involving the muscular, tendinous and fascial structures forming the perineum. When the immediate operation is skilfully done, these torn structures are united, each to each, and the perineum is practically restored to its normal condition. But after months, and perhaps years, this is no longer possible, or at least only partially so, and after extensive dissection. The retracted muscles are buried more or less deeply under cicatricial tissue, atrophy from loss of function has occurred, and the normal anatomical relation of the tissues can seldom be restored. This fact, we are sure, is too often overlooked. The perineum is quite commonly regarded as a mass of indifferent tissue, and its true anatomical structure ignored.

Finally, after immediate perineorrhaphy, the patient fully recovers during her lying-in, and need not look forward to a subsequent operation with a month blotted out from the active part of her life. Were the operation difficult or dangerous, there would be an excuse for neglecting it; but it is neither. It is perhaps as simple an operation, yet yielding as gratifying results, as there is in surgery. There is one variety of laceration which can seldom be recognized or treated primarily—the subcutaneous, or sub-mucous—and yet these tears are almost always followed by serious consequences. Either the pelvic fascia, or the muscles of the perineum, or both, give way, without a break in the mucous or cutaneous surface, and as a result the anterior rectal wall, and the base of the bladder, lose their support. Rectocele and cystocele follow. Byford has recommended for such cases, if the diagnosis has been made at the time of rupture, that deep sutures be passed with a curved needle from the cutaneous surface, and an attempt be made to draw the separated structures into apposition.

TREATMENT OF SNAKE BITES.

The recent occurrence of a case of rattlesnake bite in New Jersey, and the subsequent treatment of the patient in a New York hospital, draws attention to the state of knowledge in regard to this important subject. In one of the best hospitals in the country it appears that medical science led to no better method of treatment than that familiar to the rudest intelligences, namely, the production of profound and continued intoxication. This was carried out thoroughly, and the patient recovered. If the only adage worthy of respect in the world were that one

which asserts "*finis coronat opus*," then the case referred to is another evidence that whiskey is an antidote to the venom of the *Crotalus*. But, unfortunately, *post hoc* is by no means *propter hoc*, and the conclusion is weakened by the well-known assertion of Dr. S. Weir Mitchell, that at least seven-eighths of all persons bitten by rattlesnakes recover, and the case alluded to may show only that a man can stand a good deal of whiskey in addition to a rattlesnake bite, and not that one is antidotal to the other.

For all this, it must be admitted that there is no method for the treatment of snake bites so simple, so feasible, so easy to carry out, and so trusted as that of saturating the victim of the bite with whiskey or some other alcoholic liquor. Methods more pleasing to the scientific mind have been proposed, and ably advocated; but it remains true that none have such strong claims upon the credence of mankind, inside and outside of the profession of medicine, as what may be called the whiskey method.

In connection with this statement we would call attention to a communication on "Snake Bite and its Antidote," by H. C. Yarrow, M.D., Curator of the Department of Reptiles, in the United States National Museum, which is published in *Forest and Stream*, May 17 and 24, 1888. In this very interesting paper Dr. Yarrow gives a review of the history of the subject and describes the results of a number of experiments which he made in order to ascertain the reliability of permanganate of potash as an antidote to the venom of the rattlesnake. The outcome of the whole may be stated to be that this remedy seems to have no antidotal influence after the venom has once fairly entered the system, and that it can only be held to have the power to render the venom inactive by chemical action when brought directly into contact with it.

It might be objected to Dr. Yarrow's experiments—as to many similar ones—that the animals selected for experimentation may not be fair tests of what would happen in the case of larger animals, or of man. And it would be interesting to have some extended observations, not only of the power of antidotes, but also of the effects of untreated snake bites upon animals somewhere near the size of man. Such experiments would be more demonstrative than any with which we are familiar.

So much for the scientific aspect of the question of the treatment of snake bites; from the practical standpoint, it is interesting and it may be comforting to know that the danger from snake bites is probably very much less than the popular dread of them, and that the administration of whiskey, or some other alcoholic liquor, until distinct intoxication is produced, is a very trustworthy method of treating them. When medical science has demonstrated a method more acceptable to the scientific mind, it will be pleasant to announce it; but just now it happens that there is no method which is so deserving of acceptance and practice as that which every woodman knows, and the means for which every cross-roads can supply.

QUACK ADVERTISEMENTS IN RELIGIOUS NEWSPAPERS.

It is pleasant to be able to announce that a large religious body has recently taken official cognizance of the scandal and injury brought about by the publication in religious newspapers of fraudulent advertisements.

At the Centennial General Assembly of the Presbyterian Church, lately held in Philadelphia, a bill and overture on the subject was presented from the Presbytery of Westchester, N. Y., and the Committee on Bills and Overtures recommended the adoption of a resolution, in accordance with its suggestion, that the General Assembly, while disclaiming responsibility for or authority over religious journals not published under its direction, disapproves of "all those advertisements of patent medicine, dishonest in form, fraudulent in substance, or prejudicial to the refinement, modesty and purity of the home life."

This resolution is a step in the right direction, and we would like to see it soon coupled with a recommendation to good Presbyterians to refuse to patronize religious papers which publish—as the most influential Presbyterian papers do—absolute and unqualified false-

hoods, traps for the unwary, and advertisements which contain ill-concealed allusions to sexual matters. The editors of the three most conspicuous offenders in the ranks of Presbyterian newspapers were at the Assembly referred to, and we shall be interested to see what effect the resolutions referred to will have upon them. They have shown considerable power of resistance to appeals to their sense of right; but we shall see if this one will have any better result. Meanwhile, we believe that another Assembly might, for its own sake and the sake of religion, go beyond a resolution of disapproval and a disclaimer of responsibility and authority. To a certain extent, the credit of several religious bodies is involved in this matter, and we hope they will soon find an effectual way to mend it.

Our own efforts have hitherto been directed toward persuading our fellow editors—of religious papers—to remove these occasions of offense. We have referred to them temperately and moderately on several occasions, and have taken the trouble to mail to the editors of almost all the religious papers in the United States slips of our editorial remarks; and if, now or hereafter, we appear to speak severely, let it be understood that it is only because we think the circumstances demand plain speaking. We have not begun an attack on what we regard as a great evil, prejudicial to religion as well as to public health, with the idea of abandoning it; but determined to carry it on with as much suavity as possible, but with as much vigor as may be necessary.

PENNSYLVANIA STATE MEDICAL SOCIETY.

The thirty-ninth annual meeting of the Medical Society of the State of Pennsylvania, which has just been held in Philadelphia, was a very interesting one, in both a scientific and a social sense. The social features included receptions and entertainments of various kinds, and visits to the principal medical schools and hospitals. The scientific proceedings were marked by the reading of papers of great interest, and fairly active discussion.

One of the most important occurrences was a discussion of the relation of medical superintendents to the general management of the State hospitals for the insane, precipitated by a preamble and resolutions introduced by Dr. Hiram Corson, urging the assumption by the trustees of the general control of hospitals and the restriction of the medical officers to medical functions alone. The discussion which followed was taken part in by Dr. Schultz, of the Danville Hospital; Dr. Curwen, of the Warren Hospital, and Dr. Gerhard, of the Harrisburg Hospital. These gentlemen, and several others who took part, strongly repudiated the idea that control of the general management of a hospital for the insane was incompatible with a thorough and faithful performance of the duties of a medical officer. The outcome of the discussion was that the Society declined to pass the resolution proposed by Dr. Corson, and showed decided sympathy with the medical superintendents, at which they were directed.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

PHOTOGRAPHIC ILLUSTRATIONS OF SKIN DISEASES, AN ATLAS AND TEXT-BOOK COMBINED, By George Henry Fox, A.M., M.D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, New York, etc., complete in 12 parts. Second series. New York: E. B. Treat, (1888). Price, $2.00, each part.

This is the second issue of a work so well-known that it hardly needs to be described. It is not merely a revision of the issue of five years ago, but contains a number of new plates. Some affections which were not represented in the old issue are here considered, and the text is considerably enlarged and amplified. The method chosen for presenting the diseases of the skin in this work is one which has proved very satisfactory in the past. We recognize the fact that no plates can be prepared which exactly represent what may be found in any given case of skin disease, but there can be no doubt that such books as the one before us are calculated to assist very materially the practitioner who has not the advantage of studying dermatology under a competent teacher in the wards of a large hospital.

The present work is very handsomely executed and may be heartily commended to the patronage of our readers.

Pamphlet Notices.

[Any Reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage stamp.]

The Distribution of the Color-marks of the Mammalia. By Harrison Allen, M. D. From the *Proceedings of the Academy of Natural Sciences*, Philadelphia, February 28, 1888. 23 pages.

Strangulated Hernia. By Geo. N. Taylor, New York. From the *Medical Advance*, 1888. 16 pages.

The Pathology of Hay Fever By S. S. Bishop, M. D., Chicago. Read in the Section on Psychological Medicine and Nervous Diseases, Ninth International Medical Congress. From the *Journal of the American Medical Association*, March 17, 1888. 11 pages.

What is the Legitimate Scope of Gynecology? Annual address read before the St. Louis Obstetrical and Gynecological Society, November 17, 1887. By Walter Coles, M.D. From the *St. Louis Courier of Medicine*, January, 1888. 10 pages.

One Year of Dermatology. Report of the Department for Diseases of the Skin in Charity Hospital. By Henry William Blanc, M.D. New Orleans. 25 pages.

—The points, in this learned study of a matter of great interest to naturalists, which especially concern medical men are the idea that the distribution of the lanugo may be a guide to the disposition of eruptions upon the skin, and the proposition that lesions of various kinds may be studied as one can study the color-marks on a quadruped. After an elaborate study of the location and developmental relations of breaks in the general color of a variety of animals, Dr. Allen proposes to study the eruptions on man in the same way, and also with especial reference to the distribution of nerve and blood vessels, and the proximity of bones. The difficulty in carrying out this programme will be to secure the combination of training in natural history with clinical opportunities, which it requires. But we would recommend Dr. Allen's able paper to the consideration of specialists in diseases of the skin, in the hope that it may prompt them to carry on the study from the point to which it will conduct them.

—Dr. Taylor's pamphlet contains an exceedingly interesting description of a method for the reduction of strangulated or incarcerated hernia, which involves principles diametrically opposite to those involved in the methods usually employed. Traction and aspiration are the key-notes of his method, and they are secured by placing the patient in a position in which the hips are higher than the shoulders, and in which the action of the muscles of respiration—aided, if need be, by the hand of the surgeon or physician—tends to draw the intestine out of the hernial sac and into the cavity of the abdomen.

This method certainly appeals to one's reason, and Dr. Taylor says it is efficient in practice.

—Dr. Bishop argues for the nervous nature of hay-fever or—as he prefers to call it—nervous catarrh. His argument is interesting and convincing. The claims that hay-fever depends upon mechanical conditions in the nose he opposes on the ground that many people have diseased nasal cavities without ever suffering from hay-fever. There is much in favor of the theory which Dr. Bishop supports, and we believe that his pamphlet is well calculated to win those who read it to his views.

—Dr. Coles's address does not contain any complete answer to the question in its title, but is occupied rather with a defense of gynecologists against certain imputations which are not uncommon nowadays, and which had recently been expressed by two neurologists of St. Louis. The defense is earnest, straightforward and interesting, and gives expression to a conception of the duties and requirements of the gynecologist which must meet with general approval.

—The Department of Skin Diseases of the Charity Hospital in New Orleans was organized in October, 1886, and since that time Dr. Blanc has had charge of it. His report of the first year's work includes a table of 373 cases, and a more or less detailed account of a number of cases of special interest. One of the most interesting of these is a case of albinismus, which suggests some analogies similar to those indicated by Dr. Harrison Allen in his paper on "color-marks." Other cases might be mentioned; but we have to be content with simply alluding to them. The report as a whole is very creditable to its author, and gives promise that the famous hospital with which he is connected will do good work in promoting the study of dermatology.

Literary Notes and Queries.

[In this column the Reporter will publish short items of literary interest and questions addressed to this Journal or its readers, and answers to them, in regard to any literary matters: books, authors, places and prices of publications, etc.]

—A new journal called *Revista Braziliera de Medicina* has just been issued at Rio-de-Janeiro. It is edited by Dr. Azevedo Sodre.

—It is announced that the first number of a new journal to be devoted to diseases of the skin will appear June 1. It is to be issued by Dr. Ralph St. Perry, of Indianapolis.

Correspondence.

The Attire of Women.

Editor Med. and Surg. Reporter:

Sir:—In your issue for May 12 I find an interesting article with the above title. It states that some "French lady" (such persons usually prefer to be designated as "women") desires to have the Chamber of Deputies legalize the wearing of male attire by women. This brings up the question, why it is that women are wearing the present style of dress? Of what special advantage is it to women to wear petticoats, and how did the style originate? Somewhere I have seen the statement that women in the olden times dressed, or were dressed, in loose garments so that men could easily hold sexual intercourse with them and gratify their sensual

desires without having the form hidden away from their sight and actual contact.

This is a question which some of your readers may be able to shed light on. If such was the origin of the custom, is not the fashion conducive to licentiousness?

Yours truly, H. M. WHELPLEY.

St. Louis, Mo.,
May 23, 1888.

[The word "lady" got into the REPORTER by mistake. We object to using it as much as our correspondent does.—ED. REPORTER.]

NOTES AND COMMENTS.

Case of Cæsarean Section.

Dr. Howard A. Kelly performed his second Cæsarean section May 30. The subject of the first operation, which was noted in the REPORTER May 5, 1888, has recovered. The second operation was done for the relative indication. The patient had given birth to two children previously; the first was delivered by crushing the head with the forceps, the second was not fully developed, and neither lived. The patient has a flat rachitic pelvis, with a true conjugate estimated at about two and three-quarter inches. Craniotomy was not done because of the patient's religious belief, as she is a Roman Catholic. The child, a healthy seven-pound girl, was delivered in two minutes, and the whole operation completed in thirty-two minutes. Seven deep and fifteen superficial sero-serous sutures were used to close the uterine incision. The patient was put to bed in good condition. At last accounts she was doing well.

Fire at the University of Pennsylvania.

A portion of the Medical Hall, of the University of Pennsylvania, was destroyed by fire Thursday morning, May 31. The fire seems to have started in the pathological laboratory on the third floor, where it was fortunately discovered soon after it occurred. The destruction directly traceable to the fire is limited for the most part to this floor and the roof; but the rooms on the second floor, which are occupied by the professors as private rooms, and by the Stillé Library and Wistar and Horner Museum, were flooded with water and damaged by falling plaster, etc. The time of the fire being about the lecture hour, a number of students worked energetically and succeeded in removing much valuable property, including most of the portraits of former professors, which hung in the museum.

The loss which will be suffered is difficult to estimate, because much of the property destroyed, especially in the museum, and to a less extent in the laboratories, can never be replaced. But as nearly as can be arrived at, the loss will be between $50,000 and $75,000, which is said to be fully covered by insurance. Fortunately, the fire occurred while only the spring course of lectures was in progress. Before the preliminary course opens in September all necessary repairs to the building will have been made.

The museum is nearly one hundred years old. Dr. Casper Wistar, first Professor of Anatomy, had much to do with founding it. Dr. Horner, subsequently Professor of Anatomy, added largely to it, so that it has been known as the Wistar and Horner Museum, although there have been gathered in a great many additions from various sources. The museum also contains a large collection which belonged to the late Dr. George B Wood, and a very large surgical collection by Emeritus Professor of Surgery, Henry H. Smith. The late Professor of Clinical Surgery, John Neill, presented his collection, consisting largely of specimens of fracture and diseases of the bone. The museum was also especially rich in extremely delicate and beautiful dissections, as well as injected preparations which were deposited in it after having won prizes from the faculty, and a great many costly preparations of the brain and organs of special sense, such as the eye and ear. Dr. Leidy presented to the museum the preparations which he has made during the course of thirty years; these included a remarkably valuable series of preparations of the temporal bone, which were the result of Dr. Leidy's special study, and which showed some recent discoveries which he had made.

Michigan State Medical Society.

The twenty-third annual meeting of the Michigan State Medical Society will be held in Detroit, Thursday and Friday, June 14 and 15, 1888, beginning at 10 o'clock in the morning. Papers must be presented fully completed, in order that they may be handed to the Recording Secretary when read, thus avoiding delay in the publication of the Society's Transactions. Compliance with this request last year enabled the Publication Committee to effect an early issue. The annual addresses on Practice of Medicine and Surgery will be delivered, together with the President's Address, at the Detroit Opera House, on the evening of the first day. The public are to be invited, and it is hoped that this arrangement will permit more time to be

devoted to scientific, sectional work. Dr. T. A. McGraw is President, and Dr. George Duffield Secretary of the Society.

Prophylaxis of Syphilis.

At a recent meeting, the Academy concluded its labors on the "Public Means for Preventing the Spread of Syphilis." It was unanimously decided to adopt that portion of the report of its commission calling for the total abolition of disciplinary measures against the infected, the adoption of the best means of stamping out clandestine prostitution by warning young soldiers against its attendant dangers, and by combining the efforts of the civil authorities with those of the army medical officers with a view to the suppression of such dangers, both in town and in proximity to camps. Finally, the Academy adopted the following resolution in respect to the Navy: "Crews should be subjected to sanitary inspection prior to the ship putting into port; men found to be infected on inspection, after a voyage of sufficient length, should not be allowed to land; suspected houses, and persons leading a debauched life in naval port or ports of call should be kept under medical surveillance; and the municipal authorities of such ports should be required to keep all suffering from disease in hospital until thoroughly cured of all infectious symptoms." The discussion closed. M. Herard, President, congratulated the Academy for having initiated the agitation on this important question—agitation which is likely to result beneficially for the public health, and has aroused the attention of the public powers, and thereby paved the way for such reforms as may be deemed necessary.

Antipyrine in Chorea.

In the clinic of Dr. H. C. Wood at the Hospital of the University of Pennsylvania, both antipyrine and antifebrine have been used in a number of cases of St. Vitus's dance in children, and the results so far have been uniformly good, sometimes remarkable. Thus recently a case was shown to the class in which a week's treatment had produced almost complete quiet, although just previously there had been no decided improvement after three weeks' administration of arsenic. No difference has been detected in the action of antifebrine and antipyrine. In a recent communication to the French Academy, M. Legroux stated that he had had remarkable success with antipyrine in chorea, affirming that he has been able to reduce to a period of from one to three weeks (many of his cases getting well in a week) the duration of a disease which ordinarily lasts from sixty to ninety days. His treatment is as follows: One gramme (fifteen grains) of antipyrine is dissolved in twenty grammes (five drachms) of syrup of bitter orange-peel, and the whole is administered at one dose. Three such doses are given during the twenty-four hours. He considers it perfectly safe to give this dose to a young child, and all of Legroux's patients are now treated in this way.

In Dr. Wood's clinic much smaller doses than those used by Legroux have been used, and we are not at all sure that it is safe to give a young child forty-five grains a day.—*Therapeutic Gazette*, April, 1888.

Pengawar Djambi, or Poku-Kidang

The *Therapeutic Gazette*, April, 1888, says editorially of this drug:

"We have long used it in the physiological laboratory of the University of Pennsylvania as a hæmostatic. It was originally brought to us by Dr. Lautenbach, who had learned the value of it while working in the laboratory of Professor Schiff, at Geneva. To the physiological surgeon it is extremely valuable on account of its power of rapidly coagulating blood and forming a plug, which for the time being will stop hemorrhage even from large venous vessels. Thus, in opening up the spinal cord there is usually an excessive outpouring of blood from the torn sinuses, an outpouring which may be at once arrested by stuffing pengawar djambi into the wound. It is free from irritant properties, and we see no reason why it could not be made the bearer of antiseptic substances. Under its influences we believe that any cut surface would rapidly dry, and we trust some of our surgical readers will make a practical test and report the results in our columns."

Rupture of the Bladder in the Line of a Cicatrix of a Suprapubic Lithotomy.

At the meeting of the Anatomical Society of Paris, March 9, 1888, M. Albarran exhibited the bladder taken from an old man on whom suprapubic lithotomy had been performed five years before by Prof. Guyon. All went well in the interval with the exception of a hernia at the cicatrix; then retention of urine from prostratic trouble, at first incomplete then complete, occurred. The bladder ruptured in the line of the cicatrix, and the patient succumbed to infiltration of urine. M. Guyon lays stress upon the lack of firmness in cicatrices of the bladder, a point which he has demonstrated upon a patient for whom he did the suprapubic operation twice.—*Bulletin Médical*, March 25, 1888.

NEWS.

—Dr. Isaac Barton, of Philadelphia, has removed his office to No. 111 North Sixteenth street.

Dr. W. L. Lichtheim, of Berne, has been appointed Professor of Medicine at the University of Königsberg.

Professor Virchow has been decorated by the Emperor of Germany with the order of the Red Eagle of the Second Class.

—The Cincinnati Press Club has established permanent quarters during the Centennial Exposition of the Ohio Valley and Central States, at the Exposition Buildings, and will dedicate them on Saturday evening, June 9, with a reception and banquet.

—Miss Alice Fisher, the English nurse who has been for several years in charge of the Training School for Nurses at the Philadelphia Hospital, died of heart disease, June 3. Miss Fisher had been in failing health for some time before her death, which was therefore not unexpected.

—The *Medical Record*, May 26, 1888, says: An Italian patient in one of Dr. Shrady's wards in St. Francis Hospital, deliberately chewed a fever thermometer and swallowed the greater part of it before he was made to understand that the instrument was not intended as a medicine. Luckily, he has had no subsequent increase of temperature, which would make it necessary to risk another thermometer in that way. The rectum will be the next choice.

—The will of the late Dr. Wesley M. Carpenter, of New York, contains a clause bequeathing $5,000 to the New York Academy of Medicine, for the purpose of founding a lectureship, to be known as "The Carpenter Lectureship." The interest is to be used annually for one medical lecture, which shall be published in pamphlet form immediately after its delivery. The will provides that the Academy must guarantee the fulfilment of the conditions of the bequest, or else the proposed donation shall remain to be disposed of as part of the testator's estate. The Academy has accepted the bequest.

HUMOR.

MICROBATS.—A correspondent of the New York *Evening Post* writes from Lake Mahopac:

I stopped to talk with a man who appeared to be directing some others at the lake, and congratulated him on the successful harvest of the crop.

"Jes' so, jes' so," he said. "Well, yes, it will be a big thing this year—our folks can get any price they want."

"How is that?" I asked.

"Why, on account of them microbats in the North River ice. It's all pizeñ, and nobody will use it. Ours hasn't got any of 'em in it."

"Well, what's the matter with the North River ice?"

"Microbats, didn't I tell you! You get a microscope and examine a drop of that water; there's ten million microbats in it, and every one of 'em is a snake. They lay so close together that they keep 'emselves warm, and don't freeze when the water freezes solid. Then when the ice thaws out, there they be. Folks that drink that kind of ice-water get typhoid fever, malaria, measles and small-pox, to say nothin' of having live critters crawlin' round inside of 'em."

"But how would they work in whiskey?" I suggested; "wouldn't that kill them?"

"Now, that's something I hadn't thought of," replied the ice man. "Perhaps it might."

"Well, then," I replied, as I touched Fanny lightly with the spur, "New Yorkers, on the whole, may consider themselves safe."

OBITUARIES.

AUGUSTUS R. DAVIDSON, M.D.

Dr. A. R. Davidson, of Buffalo, N. Y., died May 25, at the age of 43 years. He was born in Ontario, Canada, and was graduated from the Medical Department of the University of Buffalo in 1878. He was a professor of chemistry, toxicology and dermatology in the Medical Department of the University of Niagara, and had been associate editor of the *Buffalo Medical and Surgical Journal.*

WILLIAM E. AIKEN, M.D.

Dr. William E. Aiken, aged 80 years, was found dead in bed at his home in Baltimore, May 31. He was for many years professor of chemistry in the Maryland Medical University, and at the time of his death was Inspector of Illuminating Gas under the city government.

SUSAN P. STACKHOUSE, M.D.

Dr. Susan P. Stackhouse was Demonstrator of Surgery at the Women's Medical College. She was graduated from that institution in 1883, and in 1887 she was elected to the chair at the college, and was said to possess remarkable abilities as a surgeon. She died at her home in Fallsington, Bucks county, and her body was cremated May 19.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

Clinical Lectures.

THREE CASES OF SCURVY.

BY FREDERICK P. HENRY, M.D.,
PHYSICIAN TO THE PHILADELPHIA HOSPITAL, AND TO THE EPISCOPAL HOSPITAL.

Delivered at the Philadelphia Hospital May 23, 1888.

Gentlemen:—I have to show you this morning three cases of a disease of malnutrition, which, before the days of canned vegetables and fruits, was very prevalent, and is perhaps more common at present than is generally supposed. The disease to which I refer is scurvy, and it is one which has become almost obsolete—certainly obsolescent—by the removal of its causes. The principal, if not the sole cause of this disease, is a want of variety in the food. It was for a long time supposed that common salt taken in large quantities for a prolonged period, had a direct tendency to cause scurvy; but this has been disproved by the observation of cases in individuals who had not eaten of salted food of any kind. The disease is now regarded as a species of starvation, or partial inanition, caused by the want of certain unknown substances found in potatoes, green vegetables, lemons, oranges and limes. Perhaps the most recent epidemic of scurvy of which we have any scientific account, occurred during the siege of Paris by the Germans in 1870–71, and it was observed in several of the large hospitals of that city, that the disease made its appearance immediately after the enforced withdrawal from the diet of potatoes and green vegetables. Numerous instances of the same sort may be found in the literature of this disease.

Dr. Garrod in 1848, was the first to propound the theory that the substance, the absence of which from the food gives rise to scurvy, is potassium; and this view of the etiology of the disease has been widely accepted, numbering among its adherents the great chemist, Liebig. The great antiscorbutic value of the potato is due to the potassium, which it contains in large amount. That the absence of potassium from the food is one of the causes of scurvy, there can be no doubt, but the view that it is the sole cause cannot be maintained; for epidemics have been observed among individuals into whose dietary potassium entered in large amount. The obscurity which surrounds the etiology of this disease, taken in connection with the fact that it frequently prevails in epidemic form, has, as a matter of course, given rise to the suspicion that it originates from, and is propagated by, infective agencies—micro-organisms. This hypothesis has not the slightest basis of fact upon which to stand, and is, as I have said, nothing more than a bare suspicion. There is, however, one fact which has seemed to lend some support to this view, viz., that the disease has been observed in infants at the breast, and the breast has been always that of a scorbutic mother. It is hardly necessary to say that a poorer milk can be scarcely conceived of than that secreted by a scorbutic woman, and this fact of the occurrence of scurvy in nursing children is, in reality, a strong confirmation of the view that the disease is one of defective alimentation.

Predisposition.—That there is a predisposition to this disease is shown by the fact, that in epidemics of scurvy a certain number of persons escape who have been living on precisely the same food as those attacked. The strong, as is to be expected, resist the disease better than the weak, while those who have recently suffered from intermittent fever or syphilis, are especially vulnerable. Bad hygienic surroundings, excessive physical

labor and depressing emotions are undoubted predisposing causes. It is probable that the two first-named causes were operative in our patients, who all belong to the laboring class. Two of them are Hungarians who have been working in a stone quarry, and the third is an Italian. None of them speak a word of English, and, therefore, it has been difficult to obtain precise details concerning their diet and mode of life. The Italian, doubtless, has been living largely on starchy food, macaroni or rice, both of which are very deficient in potash. Of sixteen alimentary substances arranged by Garrod, with reference to the amount of this substance contained in them, potatoes head the list and rice comes last.

Clinical History.—That scurvy is a constitutional, and not a local disease is shown by the fact that its pathognomonic external manifestations are preceded by a variable period of ill health or cachexia, of which the symptoms are largely identical with those of anæmia in general. In some respects, however, they are decidedly unlike those of anæmia. For instance, the countenance, instead of being pale, is of a livid, cyanotic hue, as if the blood were not thoroughly decarbonized, and it is said that direct observation has shown the blood, at this stage, to contain more than the normal percentage of coloring matter. Be this as it may, and I have had no opportunity to confirm or refute the statement, it is certain that anæmia is sure to occur sooner or later. In the patient before you, a Hungarian, who has been in the hospital for several weeks, I examined the blood on May 16, and found it to contain 2,775,000 red corpuscles per cubic millimetre, *i.e.*, 55 per cent. of the normal number, while the coloring matter was only 30 per cent. of the normal. These figures represent a very high degree of anæmia. In the second of the patients, the Italian, I examined the blood on May 22, and found a still higher grade of anæmia. The red corpuscles in this case numbered only 1,980,000 *i.e.*, their percentage was only 39. After repeated attempts to obtain enough blood for the color test, I was obliged to desist, although several deep incisions with a broad, lance-shaped needle were made in three separate fingers. The blood would at first flow readily and then stop altogether, before a good-sized drop had escaped. It seemed as if all blood in the finger-pulp had been squeezed out for no more could be obtained. The white corpuscles were certainly not increased in either case, and in the latter I believe they were not only relatively, but absolutely diminished, as I examined a great many fields without finding any, and at last, after a prolonged search, succeeded in finding *one*.

After the prodromic stage of cachexia has lasted for a period, ranging from one to several weeks, the true nature of the disease becomes manifest by the appearance of certain local affections, of which one of the earliest, and certainly the most characteristic is that of the gums. This is well marked in all three of our cases. The gums, as you see, are of a deep-red color and are swollen to such an extent that they project in fungous masses between the teeth. They are very painful and tender, and bleed on slight pressure. They may swell to such an extent as to entirely cover the teeth, or actually to protrude from the lips.

It is a singular fact that the affection of the gums is limited to the immediate neighborhood of the teeth. If there is a gap between them the corresponding portion of the gums remains healthy, and, therefore, in infants who have not yet cut their teeth, and in old people whose teeth, so to speak, have *cut* them, the affection of the gums is wanting. The other manifestations of scurvy have their principal seats in the skin, the connective tissue and the muscles. In the skin they may assume the form of small petechial spots surrounding a hair follicle, as is evidenced by the fact that their centre is perforated by a hair. This petechial eruption is present in typical form in the most recent of our cases. Sometimes the eruption appears in the form of blood-containing vesicles, which may be of such large size as to resemble the form of skin disease called pemphigus. The vesicle may rupture and its base ulcerate. Sometimes there may be large subcutaneous extravasations of blood. These eruptions, if such they may be called, are most common in the lower extremities, a fact exemplified in all three cases. In cases I and II there are considerable swelling and tenderness of both legs, which are covered with large bruise-like patches of extravasation. The largest patch is on the anterior surface of the right tibia and is several inches in length. It is of a deep purple color, and over it the epidermis is thick and desquamating. Extravasations into the connective tissue and muscles may give rise to great pain, swelling and loss of movement in the affected limb, generally one of the lower extremities. The calf of the leg, the popliteal space and the loose connective tissue around the tendo Achillis, are favorite sites of these extravasations, but the muscles of the thigh and trunk, such as the recti abdominis and the pectorales, may be attacked.

The swellings may be at first soft, later, of a board-like hardness. The skin covering them sometimes inflames and suppurates, giving exit to grumous blood, and leaving behind an ulcerating cavity. Hemorrhage in other situations is quite common, especially in the form of epistaxis, which may be of daily or nightly occurrence. In case I epistaxis occurred every night. Hemorrhages from the bowels may be spontaneous, but are more apt to follow the administration of purgatives. Hæmaturia sometimes occurs.

The effusion of pleurisy or pericarditis in a scorbutic individual, will certainly be hemorrhagic. More than a month ago I exhibited in this room a patient from whose left pleural cavity I removed twenty-two ounces of hemorrhagic effusion. I said at the time that, in my opinion, a sanguinolent pleural effusion was not so much an indication of tuberculosis of the pleura as of a scorbutic diathesis. This patient has since died, and at the autopsy, no tubercle was found in either lungs or pleura.

In severe cases the bones may be affected in various ways. Either spontaneously or as the result of slight injuries which, in a normal constitution, would be followed by no such effect, extravasations of blood take place beneath the periosteum which, if extensive, may lead to partial necrosis of the underlying bone. The tibia is the bone most frequently affected in this way, doubtless on account of its exposed situation. Sometimes the epiphysis of a bone is separated from its attachment to the shaft, by the extravasation of blood between the two portions. This is most frequently observed in the ribs at their point of junction with the costal cartilages. The first symptom of this complication is a painful and tender swelling at the point of junction of rib and cartilage, followed by abnormal mobility and crepitation of the affected spot. Several ribs on either side may be affected in this manner, the result of which may be that the sternum, deprived of its usual supports, sinks inward toward the spine. It is said that reunion of the separated portions will occur in case of recovery; but when the disease is accompanied with such changes as these, it generally ends fatally.

The callus uniting recent, or even very old fractures, is apt to soften in well-marked cases of scurvy. Inflammatory hemorrhagic effusions into the joints, especially of the knee and ankle, have been observed and are known as scorbutic arthritis.

A peculiar affection of vision, a form of amblyopia known as hemeralopia, has been observed in a number of cases. By hemeralopia is meant an inability to see distinctly except in a bright light. Another name for the affection is night-blindness. It has been most frequently observed in sailors who have been long exposed to the glare of a tropical sun while suffering from scurvy or greatly debilitated from an improper supply of food. It is said that the ophthalmoscopic examination of such cases does not yield any positive results. The disorder of vision is doubtless caused by exhaustion of the retina, which, in order to perform its function, requires the stimulus of a strong light.

Although probably no case of scurvy runs its course without abnormal rise of the body temperature, fever is not an essential feature of the disease, but is secondary to the inflammatory complications of gums, skin, connective tissue, bones, joints, etc. In all three cases the temperature has been above the normal, and in one it was 103° at the time of admission.

The origin of this disease has naturally been sought in the blood, but thus far no definite change has been detected in the composition of this fluid; that is, no change not met with in other forms of anæmia not attended with scurvy. The conclusions of chemists with reference to the composition of the blood are diametrically opposite. Thus one set of chemists has demonstrated an increase of the salts of the serum, especially the chloride of sodium, to double the normal amount, while another has been able to prove that they are diminished. A more definite result, certainly none could be more indefinite, might be reached by the analysis of the solid tissues, especially the blood-vessels, connective tissue and muscles.

Treatment.—If diseases were divided into preventable and non-preventable, scurvy would certainly head the list of the former, for there is none concerning the prophylaxis of which we have more certain rules. Without entering into particulars, which may be readily inferred from what I have said of the causes of this disease, it may be asserted that scurvy will never make its appearance, either in laboring or idle men, who are supplied with plenty of nutritious food. From an anti-scorbutic standpoint no single article of food can be compared with the potato. In the treatment of the disease itself, immediate attention should be paid to the gums; for until they are in a comparatively healthy state, the first two steps in the digestion of solid food, mastication and insalivation, cannot be taken. While life may be supported indefinitely by milk, eggs and soup, such life

is not one of hard work. Solid food is the prerequisite of solid work.

Gargles of solutions of potassium chloride and tincture of myrrh will be found of service; also, painting the gums with strong solutions of nitrate of silver, or with the solid stick. The strong fetor of the breath may be corrected by adding carbolic acid to the mouth wash. Two or three grains to the ounce will be sufficient. Internally, lemon juice should be administered. One of our patients has greatly improved while consuming six lemons daily. If iron is tolerated, it may be administered in the form of Blaud's pill, which contains potassium as well as iron.

PELVIC ABSCESSES AND THEIR DIFFERENTIAL DIAGNOSIS.

BY ARPAD G. GERSTER, M. D.,
PROFESSOR OF SURGERY IN THE NEW YORK POLYCLINIC, ETC.

Pelvic Abscess; Differential Diagnosis.

GENTLEMEN:—The patient before you, a man about thirty-three years of age, has an extensive pelvic swelling located to the inner aspect of the os ilium on the right side. It was preceded by a sickness which the patient called lumbago, and also by lead poisoning which caused considerable intestinal trouble. The doctor who brought the patient says he punctured the fluctuating swelling and found pus. Therefore, the answer to the question as to the character of the swelling seems to be clear that it is an abscess. As the swelling developed gradually, it is probably a cold abscess.

Before proceeding to the question of treatment, we will have to find out if possible the cause of the abscess. First of all, we may have to deal with a perityphlitic abscess. The patient has had bowel trouble accompanying lead colic. The cæcum is one of the parts involved in lead colic, and one of the most constant symptoms is constipation. This patient has been constipated. There may, then, have been an enteritis at the cæcum, an enteritis which extended to the vermiform appendix, and which lead to agglutination, perforation, and the formation of an abscess in the right groin. This may have worked its way in the usual manner, raising up the peritoneum until it came beneath the transversalis fascia and the skin where it now is. It was at first, according to all appearances, a retro-peritoneal abscess.

Another possibility in the case is spinal trouble. He has suffered from what he calls lumbago; it may be therefore that the abscess has had its origin on the lower portion of the spine, or on the sacrum. Cold abscesses forming there sometimes work their way exactly as do retro-peritoneal abscesses and appear above Poupart's ligament beneath the skin.

A third possibility is disease of the right kidney, a perinephritic abscess, for the pus in these cases occasionally, but not as a rule, works its way beneath the peritoneum until it reaches the integument above Poupart's ligament. These abscesses generally point in the loin, but while that is the rule there are exceptions which should be noted, just as exceptions to the rule that perityphlitic abscesses point above Poupart's ligament are occasionally seen. I had such a case a short time ago, in which the question was not decided until after the operation whether the abscess was perinephritic or perityphlitic. It had pointed in the loin. After the operation it became clear that the case was one of perityphlitic abscess; there was nothing abnormal about the kidneys.

We shall have to carefully examine this patient to determine whether he has kidney trouble, spinal or pelvic trouble, or intestinal trouble as the cause of this abscess.

When asked to state where he felt his lumbago the man indicates the junction of the sacrum and os ilium on each side. He favors the right leg in walking. The further fact that the pain ran around both sides and shot down into the thighs would lead us to suppose that the original trouble was near the median line—that the affection developed in the centre of the posterior aspect of the spine or pelvis.

The swelling, as you see, is located just above Poupart's ligament on the right side, and fills the entire iliac fossa. When the patient flexes the legs and the thighs I can make deep pressure, and find that the swelling extends to the median line. It is very large, and is distinctly fluctuating. We have to deal with a much larger abscess than the outer appearances would indicate. The loin itself is empty. If we had to do with kidney trouble I believe there would be distinct swelling in the right loin. His water, he says, has always been clear, and that which he has passed to-day is normal. So far as it goes that is evidence that there is no kidney trouble. We may regard the question as having resolved itself into two: a question of pelvic abscess due to spinal or pelvic disease, or one due to perityphlitis.

The patient says he has had the pain which he attributes to lumbago for four or five months. It is, therefore, a chronic affair. His general condition has become lowered.

If we can find some physical signs of pulmonary trouble it will go toward confirming the view that he has tubercular disease of the bones of the pelvis, probably of the os sacrum.

The patient says that he had pleurisy two years ago. This is a strong link in the chain of evidence. I am going through the evidence with you methodically to demonstrate how to arrive at a diagnosis. I do not simply diagnosticate pelvic abscess. That is not sufficient. We must be more precise in diagnosis if we would be of some use to the patient. The doctor who would have examined that abscess alone and not the internal organs also would not have earned his fee. If you want to treat your patient successfully, you must know *all* that you have to treat. If you do not know the original cause of the trouble, your treatment will be mere haphazard, chance work.

As you see, this man's chest is not symmetrical. There is a sinking in on the right side. There is distinct dulness in the axillary line corresponding to the base of the right lung, both anteriorly and posteriorly. The respiratory sounds at the base of the right lung are diminished. It can not be pronounced normal vesicular breathing. There is slightly bronchial breathing at the right apex.

I would diagnosticate induration of the right lung, old deposit of pseudo membrane of tuberculous nature around the base of the right lung. And I would also diagnosticate a cold pelvic abscess dependent upon trouble in the sacrum or lower portion of the lumbar spine. Still I would make a reservation in the diagnosis, as there is a possibility which can not be absolutely excluded. If this man had not told us that he has had lead poisoning and lead colic I should have made this diagnosis without any reservation. But having been told that he had trouble with the gut, I would not exclude absolutely, and without any reservation, the possibility of perityphlitic abscess, although the chances of its being such are very slight indeed. Perityphlitic abscess sets in with an acute attack which resembles peritonitis. In almost all instances it begins with abdominal distress, very acute pain, and a rapid development of a tumor in the groin.

Here is a large pelvic abscess. Is it proper in a case of this kind to drain the abscess? that is the question. If I had the patient in care at a hospital where there were all the guarantees of a careful and competent management of the wound, after the incision had been made, I possibly would do the operation, because if the abscess were incised and drained, the chances would be that the walls would afterward collapse, come in contact again, a sinus would be left which could be kept sweet by proper dressings, and the man would be enabled to go about with comfort. But I confess that I do not like, without urgent indication, to open large abscesses which have their origin in disease of the spine or pelvis. When the Listerian treatment first arose its author laid great stress on the statement that these cold abscesses, originating in hip-joint disease of the spine or pelvis, etc., could be incised without danger, and that the teaching of old-time surgeons not to meddle with cold abscesses was no longer valid. For a time we all believed with Lister, but we have again come to modify that view. We have come to say that such abscesses should be incised only for some urgent indication; for instance, on account of their great size, impeding locomotion. I have seen such abscesses swell up the thigh six or eight times its normal volume, filling out the gluteal and adductor region so that the patient actually could not walk. In such cases, of course, an incision would be proper. In other instances, the abscess may threaten to perforate in the vicinity of the anus, which would be very unfavorable since the fæces would be likely to infect the abscess cavity.

There may be other urgent indications for the incision of a cold abscess. We have seen a case here in which the pain was so acute that the patient sought the counsel of the neurologist who treated him for sciatica. When he was turned over to us we found a cold abscess, which had been working its way out of the pelvis, through the greater sciatic notch. Then we knew that the patient did not need the treatment of the neurologist, but rather of the surgeon. In this case we would evacuate the abscess on account of the great pain it is causing.

Shall we evacuate the abscess in this instance by incision or by another method, which, although not perfect, is a very good substitute for incision? If you incise the abscess, it cannot heal until the disease causing it has healed. The causal lesion, however, is not likely to heal very rapidly, therefore it is to be presumed that the fistula will remain patent and the discharge will continue for a very long time; and if you want the fistula to remain in good condition it will be necessary to keep it dressed antiseptically all the time. If you should leave off the dressings, or allow the patient to manage the wound himself, you might be sure of sep-

tic material extending through the fistula up to the original trouble, whether in the spine or in the pelvis. That should be avoided by all means. Free incision and drainage by a tube would necessitate your constant care of the fistula until it closed. If you cannot make up your mind to the second part of this duty you should not choose the first. If you incise the abscess you thereby put yourself under obligation to the patient to care for the fistula afterward. It will not do to cut open the abscess and let the patient shift for himself, or turn him over to somebody else; for on you rests most of the responsibility for everything that happens subsequently.

Cold abscesses are divided into two classes, those which are becoming larger and in which there is a continuation of the disease from which they originated, and residual abscesses, or those which have remained after the bone disease which caused them has healed.

In the latter class of cases, although the bone disease has healed, there may remain in the abscess cavity some bone detritus to retard the absorption of the pus and union of the walls. No new pus, however, is thrown into the cavity, the old pus corpuscles undergo a peculiar disintegration, the contents of the cavity become ropy, and are tinged a reddish color. Furthermore this ropy serum shows a peculiar glitter in reflected light. If you examine some of the contents of the residual abscess under the microscope you will detect numerous little cholesterin crystals as the cause of this glitter. If you empty the cavity you will find that it will not refill, for the cause of the abscess, he disease in which it originated, has been cured. I had such a case in a man who had a swelling occupying the adductor region of the thigh. Having been present nearly twelve years, I was led, as well as several other surgeons, to make the diagnosis of cystic growth. But when I came to operate I could not find the cyst sac; the walls consisted of the muscles and fascia surrounding the swelling. I then cut into the cavity, evacuated a large quantity of material like that just described, inserted my finger and found a sequestrum of bone which was found to have been cast off from the lesser trochanter. The man then remembered that many years before he had had some trouble in the trochanteric region which was accompanied by high fever, and which confined him to the bed. The sequestrum was less than half an inch in its longest diameter, was rounded off on one side and rough on the other, and corresponded to a notch in the lesser trochanter. In a case of that kind, of residual abscess, you need not hesitate to evacuate the contents, for the bone disease having healed, the cavity will not refill, and the walls will close. But if the bone disease remain and you make an incision and drain the abscess cavity, it will go on to discharge pus, infection may take place through mismanagement, the bone disease may extend, the patient become hectic, and, although he may have been doing fairly well before you incised the cold abscess, he may rapidly succumb to the additional inflammation which your incision gave rise to. Therefore I repeat, do not be too rash in interfering with cold abscesses.

In this case I would advise the patient to go to the hospital, where he will be kept in bed a week or ten days; then we shall disinfect the parts thoroughly, plunge a large-sized trocar into the abscess cavity, allow as much of the contents to escape as will, guarding at the same time against the entrance of air into the cavity, and possible infection; then inject a certain quantity of iodoform after Verneuil's method which you have seen me adopt on several occasions. The fluid consists of a solution of five parts of iodoform in one hundred parts of ether, or the emulsion recommended by German authors, consisting of a similar proportion of iodoform and glycerine. The latter can be used in larger quantity than the former, as the injection of a large quantity of ether into an abscess might produce serious ether intoxication.

After the abscess cavity has been injected with this emulsion it will gradually refill again, and possibly a second time, but if the injection be repeated the contents will finally become a clear, limpid fluid, which has no resemblance to pus. The refilling becomes slower and slower, and the patient derives a great deal of comfort from the procedure. I think the healing of the primary cause of the abscess may also thus be hastened, especially if the iodoform could reach the site of the bone disease.

Were the cause of the abscess situated in an accessible region the surgical treatment would be different. In that event I would slit open the whole abscess and scrape out all the tuberculous lining with a sharp spoon. Then I would search for the fistula leading down to the bone (supposing that the pelvis was diseased near the crest of the ilium), I would lay it open, and remove with the chisel and mallet all the diseased bone, and then close the wound as a freshly made clean wound, and I would expect primary union and healing after the one operation. If you

have to deal with tuberculous bone in *accessible* portions of the body, remove the diseased portion of bone at the same time when you open the abscess, and rapid cure will follow. But if the tuberculous affection be *inaccessible*, you should be careful about interfering with the cold abscess to which it gives rise. Those of you who received your surgical training twenty-five years ago, as I did, have found that the old time surgeons knew very well whereof they spoke when they gave the injunction not to meddle with cold abscesses. They could not explain why it was dangerous to incise cold abscesses, but there was common sense and good observation at the bottom of their teaching, and although for a time the rule which they had established was seemingly invalidated, yet we see it again re-established to a great extent. And so it is with many other things which seem for a time to be overthrown by new truth; at last we have to go back and admit that the grain of gold contained in old teachings must not be thrown away with what is evidently but rubbish.

Communications.

Address in Mental Disorders.[1]

BY HORATIO C. WOOD, M.D.,

CLINICAL PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM IN THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA, ETC.

When primeval man by means of his split flints had so subdued the opposing forces of nature that he had leisure to think of things other than the immediate supplying of his wants, his attention was, no doubt, most painfully arrested by the torments of sickness. In that hour was born that science, which in the lapse of ages has developed, until now it constitutes the vast mass of discovered fact, established deduction and bold speculation which we know as the science of medicine. At first, the outward manifestations which were called symptoms attracted the observer. Ages probably passed by before these symptoms were in the consciousness of the race associated into well defined groups. Then the underlying causes began to be sought out. Morbid processes were investigated, and so step by step the study progressed until at present, pathology has so far been perfected that most disease-processes are understood, and when we speak of typhoid fever or any other equally well-known affection we refer not to a group of symptoms but to a definite disease-process. In mental medicine the pathological problems are so recondite that hitherto they have in great part baffled investigation; it is indeed an open question how far we shall ever be able to apprehend the minute structural changes which are connected with morbid mental action; there are problems in the settlement of which our finest microscopes are mere blundering, useless tools. To our utmost study the human spermatozoa are nothing but irregular, transparent specks of protoplasm not to be distinguished one from the other. Yet the records of past generations are written in those formless particles, and in them also are enfolded the potentialities of future successions of men. From one shall come forth a demon, from the other a saviour of the race. Who shall solve the riddle of their construction? Helpless and hopeless are we. Almost hopeless is it that we shall ever understand the infinitely delicate changes which take place in the complex protoplasm of nerve cells, and be able to see the waves of emotional and mental excitement or paralysis which sweep over the individual, or to recognize the alterations in nervous protoplasm gone mad. Or our so-called mental diseases are simply groups of symptoms, which may, for ought we know, in different cases arise from essentially different pathological processes. In one individual suffering from paralytic dementia the depression of melancholy clouds the life, whilst another man with apparently the same brain lesion revels in the wild exaltation of the mania of grandeur.

For the purposes of discussion, we must at the present stage of our knowledge of insanity, give names to certain symptom-groups, but for the purpose of clear thinking it is essential for us to remember that these symptom-groups are not diseases, but associated symptoms which may in different cases depend on essentially different causes. Is a melancholia which is produced by impacted fæces and relieved almost at once by the clearing out of the rectum (*Amer. Journ. of Insanity*, XLII, p. 264), the same disease as a melancholia depending upon hidden and irremovable causes in the nerve centres? It is odd that alienists of wide culture and ability have hot disagreements in regard to the diagnosis of a case. Thus in a review of Professor Seguin's Opera Minora, Dr. Kiernan, of Chicago, exclaims of a case reported by Seguin as a maniac, "whatever the psychosis might have been it certainly was not mania." If mania were a distinct

[1] Delivered at the meeting of the Pennsylvania State Medical Society, June 7, 1888.

disease it is hardly likely that a neurologist of the experience and culture of Dr. Seguin would not be able to recognize it. If mania be not a distinct disease, but a mere set of symptoms, surely the vehement assertion made by Kiernan is little less than an absurdity. The truth is that the thought of modern alienology is pervaded by the fallacy that our symptom-groups are diseases.

Symptomatology in any department of medicine is a study of the first importance, but in mental medicine it at present almost bounds our horizon. To the study of this symptomatology men are urged not only by the needs of the insane but also by the neces sities of the sane.

If there be one thought more than another which ought not to be forgotten, it is that the human mind diseased is the human mind still. The coming on of insanity marks not the appearance of a new entity or a new force. The old entity or the old force simply goes astray. It is the failure to grasp this clearly which has lead many a lawyer to say to the expert: "You crazy doctors believe that everybody is insane," and has occasionally betrayed the unwary alienist into acknowledging that this assertion is true. I say distinctly that it is not true. Sanity is the condition of the great bulk of mankind, but the impulse, the mood, the failure of judgment, the lack of coherent thought—the various symptoms which constitute the chaos of disturbed intellection find their counterparts, or rather their germs, in every healthy mind. So long as these impulses, moods, etc., can be dominated by the will of the individual, just so long are they simply the weaknesses of humanity; but when the will of the individual is powerless before them, then is that individual insane. The passage from one state to the other may be so gradual that only to omniscience is it possible to say when the line between sanity and insanity, responsibility and irresponsibility is crossed.

Insanity so terribly affects the relations of men that it very frequently is the centre of the legal battles whose arena is our courts. Not rarely the keenest and most thoroughly trained intellect is baffled in attempting to decide how far responsibility should attach to the alleged criminal, or how far the original will of the individual has entered into the instrument which purports to be his last will and testament. When this is remembered, how utterly absurd appears to be our system for deciding the mental condition—a system which we have inherited from the times of oppression and of violence. Twelve men, perchance honest, of a certainty, many of them uneducated, and probably all of them ignorant even of the ordinary principles of medicine or of mental action; one judge, learned in the law, and bound in the iron hoops of legal prejudice and legal methods of thought, unacquainted with the science of medicine, and mayhap with the laws of mental action; two lawyers, sharp, trained in every device for brow-beating and baffling witnesses and in every crafty method of hiding the truth and of misleading the ignorant, contending one with the other; experts, chosen without guarantee of their knowledge of the subject, hired by one side or the other, possibly dishonest, certainly liable to have their view of the case affected by the glass through which they have looked at it. This is the machinery which in theory is to perpetuate justice, but which in truth in a large proportion, if not the majority of cases, works out the wrong. With such a system and such a method is it a wonder that the decisions of our courts in questions of insanity are a laughing stock among those who know? Is it a wonder that the sane man is so often judged insane, while the lunatic almost as often has the stamp of sanity put upon his untoward acts?

Is it a wonder that those who have seen much of this so-called justice grow cynical and look upon legal procedures as farces which, alas, but too often end in tragedies? Not many years since two lawyers of eminence came into my office, and laid a certain case before me, desiring that I should go upon the stand and declare that their client was sane. After listening to their statements, I said, "This man is absolutely insane, and you cannot find on the two continents an individual who is at once honest and capable who will not give you an opinion similar to mine. There is no room for doubt in the case. If, however, you want to win, all that you must do is to call in no experts, declare that you do so because doctors and experts are fools, browbeat and confuse, as much as lies in your power the expert witnesses on the other side, and then appeal to the jury that this American citizen shall not be deprived of the rights for which the immortal Washington, Adams and Jefferson contended, and for which heroes innumerable have fought and died." They took my advice. The witnesses were confused, the jury was dazzled by the eloquent appeals. The judge made a charge which the newspapers of the day lauded to the skies, but which seemed to me veritable foolishness, and the man was declared sane. Shortly afterwards, in the wreck of his intellectual power, he had still sense enough to perceive that in

order to protect himself from himself the restraints of an insane asylum were essential, and I believe that he is still a voluntary inmate of such an institution.

To the truculent barons that gathered around King John at Runnymede, personal liberty seemed the one point for whose preservation all law should exist. But times, although not laws, have changed, and to-day the danger to the State is not that personal liberty shall be restrained, but that it shall degenerate into license. The spirit of the barons still lives in our legislation and in our public opinion in regard to insanity. Pamphlets, newspapers, lunacy commission reports, all portray the hardships of depriving the lunatic of his freedom, and men grow eloquent concerning the danger lest sane men shall be shut up in asylums. The medical profession seems to be in the eyes of the public an avaricious monster lending itself for gold to any nefarious design. Laws have for their basis the idea that men and women are for criminal purposes habitually incarcerated in asylums. The fear of this is, however, to my thinking but a survival of mediæval feelings and mediæval possibilities. It is now nearly twenty years since I began to study insanity as a specialty, and I have never yet known a case in which a person was improperly placed in an asylum, though I have known cases in which persons whom I believe to be lunatics have been set free by lunacy commissions. More than this, I have had personal knowledge of almost every kind of prejudice as the result of the failure of the law to give protection *from* the lunatic. I have known the prisoner whose craziness should have been recognized allowed in his cell weapon and opportunity for mashing out without cause the brains of an unsuspecting keeper—an almost raving lunatic suffered to pour sulphuric acid upon his victim—a mother permitted to cut the throat of her own offspring and to die by her own hand; beside them, a father scarcely stopped by neighbors in time to prevent the final completion of rape upon his daughter—another father allowed to blow out the brains of the helpless little child kneeling before him in an agony of prayer for life. I might extend the catalogue, but I forbear. Waste of property, dishonor, death by murder and suicide—these constitute a long line of perpetually repeated tragedies which might and which ought to have been prevented by early recognition of the mental condition and sequestration of the insane criminal. On the one side, the lunatic himself and his insane victims call aloud for protection from the wild-beast like fury of the maddened brain. On the other is the bugbear of personal freedom. Let, however, a crime be committed, and here, at least in Pennsylvania, that law which has made protection so difficult, cries for blood, although punishment has very little deterring effect upon the insane, and the only protection which is afforded to the community by hanging the insane murderer is a protection from his individual acts. A dead lunatic is certainly a harmless lunatic. The Pennsylvania law is wise in that it does give the judge the right to perpetually incarcerate the lunatic who has once been acquitted on account of his lunacy. But the general workings of the modern law is shown in the case of B. recorded in a recent number of the *American Journal of Insanity*. This man was a moral imbecile driven by a furious impulse to torture and kill, whose greatest pleasure was to tie up horses in the woods and gradually whittle them to death, to mutilate living cats, torture chickens, break the legs and tear to pieces, whilst living, small birds, and who, when opportunity offered reached the very heaven of his joy by assaulting, torturing, killing human beings. When twelve years old he took his toddling brother into the woods and nearly flogged him to death. He attempted to strangle a younger brother and to smother his infant sister; had stabbed various people, essayed to suffocate a harmless imbecile, and to choke another inmate of the asylum, and committed at least two criminal assaults on women, the last during an escape from the asylum. Tried for this last offense in spite of the efforts of alienists, the patient was convicted and condemned to six months' imprisonment. His conviction of course was tantamount to a legal declaration of sanity, and the judge in sentencing the prisoner told him that at the end of the three months he would be a free man.

The problems growing out of the relation of insanity to crime are exceedingly difficult, and I do not propose to-day to say more about them except to express my conviction that the present system of trial would be improved by the presence of an alienist upon the bench as an associate judge, or by the reference of the question of insanity in criminal, as well as in civil cases to a commission, whose report might probably be subject to review by the judge.

Possibly, the public opinion which at present demands the hanging of insane people is not so far wrong as some of us think, but certainly there can be no question as to the evils which have resulted from the systems

of civil insane commissions. As proof of this I shall cite two recent cases which I believe have not been before published, and in which I have been personally concerned. The first case is that of Dr. Martin Weaver, an elderly gentleman living at Germantown. The petition asking that Dr. Martin Weaver should be declared a lunatic was filed by his nephew, but the circumstances were such that the pecuniary interests of his daughter, Miss Weaver, were chiefly involved in the declaration that her father was a lunatic.

Twelve witnesses in all, including the party who served the notices were examined on behalf of the petitioner, and but two or three of these witnesses testified to any knowledge of the alleged lunatic during the three years preceding the inquisition. On the other hand, twenty-two witnesses testified in the most positive manner as to the sanity of Dr. Martin Weaver covering a period from his boyhood to his present advanced age of eighty-one years. The following well-known physicians affirmed without qualification the undoubted mental capacity of Dr. Weaver, after they had made a personal examination of him: Dr. D. Hayes Agnew, Thomas G. Morton, Dr. John B. Chapin of the Pennsylvania Hospital for the Insane, Dr. John C. Hall of the Friend's Insane Asylum, Dr. Henry M. Wetherill of the Pennsylvania Hospital for the Insane, Dr. Charles K. Mills, and Dr. J. R. Landis, the family physician of Dr. Martin Weaver for the past six consecutive years. Further, no less than eight well-known lawyers testified from personal knowledge as to the entire ability of Dr. Martin Weaver and his capacity to manage his own business. Not a single physician or expert on insanity was called to testify that Dr. Martin Weaver was insane. Nevertheless, the jury decided Dr. Martin Weaver to be insane in the face of the strongest protest from the commissioner, who was acting as judge in the case. The court of common pleas after hearing the whole case set aside the report of the jury as contrary to the evidence, but when the matter was carried to the Supreme Court of Pennsylvania, it was then decided that the common pleas court had not the power to set aside the verdict, which still stands. I have myself in two long interviews studied the mental condition of Dr. Weaver, and although he is *de jure* a lunatic, he is *de facto* sane.

Living near by to Dr. Martin Weaver was an adult imbecile man, whose father died after a long period of chronic lunacy. Miss Bessie Weaver, the same woman who was involved in the previous suit, was married to this young man in the city of Camden, and suit was afterwards brought in order to have the marriage set aside on the plea of the imbecility of the man. —— was afterwards examined by Dr. Chase, of the Norristown Asylum, and myself, and we pronounced him without hesitation an imbecile of a low grade. Without going into the details of our examination, it suffices for the present to state that, I questioned him to discover whether the marriage had been consummated or not, but did not succeed in making him clearly understand what I meant, although I judge that there had been no consummation of the marriage. Although he had been sent to school until he was twenty-two or twenty-three years of age, he was unable to give change for a dollar without counting on his fingers, and in no way could he completely give the change for a two dollar bill. He was without doubt a harmless, docile imbecile, yielding like putty to any one that he would come in contact with; yet the jury was divided, about half of them declaring that he was able not only to take care of himself, but his inherited estates, which amounted to some hundreds of thousands of dollars. In the absence of any agreement he remained in the eyes of the law sane, and I am informed that this case was settled by the payment of a large sum to Miss Weaver, never to come near the imbecile. I understand Miss W. has a very high opinion of our legal methods.

The law of Pennsylvania provides two methods of declaring a patient insane by civil process. Thus one act requires that on statement in writing of any respectable person that a certain person is insane, and that the welfare of himself or of others requires his restraint, it shall be the duty of the judge to appoint immediately a commission which shall inquire into and report the facts of the case. This commission shall be composed of three persons, one of whom at least shall be a physician, and another a lawyer. In their inquisition they shall hear such as may touch the merits of the case, as well as the party complained of or his counsel. If in their opinion it is a suitable case for conviction the judge shall issue his warrant for such disposition of the insane person as will secure the object of the measure. According to the second act, upon the application in writing of relation by blood or marriage, or of a person interested in the estate, a commission empowering one or more persons as commissioners may be issued by the court of common pleas by virtue of which the sheriff is required to summon such number of per-

sons, not less than six nor more than twelve upon the inquest, as the circumstances of the case may seem to them to require. When this inquisition after examination has declared the person a lunatic the aggrieved person may traverse the decision, provided such traverse be fulfilled within three months after the declaration of the inquisition. The power of traverse consists of a trial before a jury in the court of common pleas to determine whether the mind of the alleged lunatic be deranged to such an extent as to disqualify him from conducting himself with perfect safety to himself and others, disposing his own affairs, and discharging his relative duty.

It so happens that I have never seen practiced the method of declaring a person insane by means of a commission of three persons as directed by the act here first spoken of, and its use must be very rare; the second plan being almost universally pursued probably because the law directly affirms that under it the estates as well as the person of the insane man pass into the hands of the trustees. This second method is practically a jury trial and possesses all the inherent faults of such a trial. It is hardly necessary to recall attention to these faults. They may be summed up as existing in the expensiveness of the method, and the absolute impossibility of obtaining just decisions in regard to intricate scientific questions, amid the ignorance and prejudice of twelve men drawn almost invariably from the lower walks of life and under the influence of trained minds trying to mislead. "Of course he ought to be confined in the asylum," says the lawyer with a sneer, "he pays them forty dollars a week," and the jaw of the juryman sets as plaster-of-Paris sets in the mould of the sculptor.

All the legislation that would be required to make the laws of Pennsylvania in regard to the civil side of insanity worthy of some respect would be to abolish the second method of declaring people insane, and to require that the decision should be allowed to rest with a commission consisting of three persons, one of whom shall be a lawyer, one a doctor, and one a general man of business. I believe myself that the decision of such a commission should be finally subject only to review by a bench of judges who, under restrictions, with which it is not necessary to here occupy time in discussion should have the power to overrule it. In insanity cases I would do away entirely with the *habeas corpus* and its accompanying jury trial. Owing, however, to its close connection with political liberties in the past, the jury is still a fetich which is worshipped probably by the bulk of the legal profession and the majority of the American public. It remains, however, a feudal relic utterly unsuited for many of the emergencies and complex relations of modern life. There is even a widespread belief that the man has a constitutional right to a jury trial. It is hardly necessary to say that this is not correct, that the constitution simply guarantees that the man shall not be deprived of his liberties without due process of law. What this process of law shall be is left to the legislature.

Perhaps, however, I am all wrong in thinking that the term administration of justice, applied to the processes of the law, ought to be considered anything more than an euphemism. Wiser, no doubt, was the dictum of a very famous lawyer which I heard publicly quoted by Mr. George Biddle with approval. According to this dictum the law does not exist for the purpose of doing justice, but for the purpose of preventing men from cutting one another's throats. That in regard to insanity, law in America is not always successful, even in the latter aspect, is shown by a case of which I have cognizance in which a jury acquitted a man of homicide on the ground of instantaneous irresistible impulse, although the murderer had armed himself, traveled nearly one hundred miles with the apparent intention of killing his wife's paramour. This case is only one of many that might be cited as an illustration of the fact that the results of a jury trial depend much more upon the sympathies of the jury than upon the justice of the cause.

I insist that not only for the purpose of justice, but for the purpose of control, the Pennsylvania law in regard to insanity still needs modification, a modification which to my thinking ought to be easy of accomplishment, because it would consist chiefly in the abrogation of an old law, which in spirit is discordant with the recent act. Let at least in all civil cases the question of sanity or insanity of an individual be decided by a properly constituted commission, and it may happen in coming decades that justice shall invade even the province of the criminal law. Is it not fitting for this association to move this matter, and would it not be well to appoint a committee who should have power to represent this body? I therefore offer this resolution:

Be it resolved that the President be directed to appoint a committee of —— members who shall confer with the State Committee of Lunacy, and if in the concurrent opinion of

the committee changes are advisable in our laws relating to lunacy, shall have power to represent this body in obtaining such legislation.

NEPHRECTOMY FOR NEW GROWTHS.[1]

BY JOHN B. DEAVER, M.D.,

DEMONSTRATOR OF ANATOMY AND LECTURER UPON SURGICAL ANATOMY, UNIVERSITY OF PENNSYLVANIA; ATTENDING SURGEON TO THE PHILADELPHIA, GERMAN, AND ST. MARY'S HOSPITALS, PHILADELPHIA.

Mr. President and Gentlemen:—The two most important and common forms of new growths of the kidney are sarcoma and carcinoma; fibroma, lipoma, myxoma, angioma and adenoma are occasionally met with. Sarcoma is more common than carcinoma: carcinoma is the form of malignant disease usually met with as a congenital affection. Carcinoma is very rare in children, being more common in old age. A sarcomatous or carcinomatous kidney may grow to an enormous size; this is true especially in children. Roberts notes a case in a child of six years, in which the tumor weighed thirty-one pounds. In the growth of the tumor its tendency is to extend into the pelvis, and to frequently obstruct the ureter. Both kidneys may be the seat of malignant disease, but it is rare for both organs to be attacked at the same time. Secondary deposits are found in many of the cases that die of the disease. The renal vein often becomes involved, and through it the cancer may grow into the vena cava, thus furnishing a focus from which infarcts may be carried into the lungs and liver. Fibromata usually do not give rise to any special urinary symptoms. Wilks cites the case of a fibroma of the kidney in which hæmaturia and pain in the loins had existed for ten years, the tumor being present for six years; death was preceded by the symptoms of uræmia. Neither does lipoma, myxoma, angioma or adenoma occasion any urinary symptoms that would be indicative of either form of growth, unless they reach such a size as to occasion compression of the renal vessel or ureter, in which event the enlargement could most probably be detected, yet the nature of the growth could only be determined after its removal. The symptoms of malignant disease of the kidneys are the presence of a tumor, hæmaturia and pain. Hæmaturia occurs in fully half of these cases, being intermittent, the amount of blood lost depends upon the patient's habits and occupation. The blood sometimes forms clots in the ureter; a specimen of the urine under these circumstances will show a cast of the ureter. In the interval between the attacks of hæmaturia, the urine contains but little pus and albumin; occasionally tube casts. Fragments of cancer structure in the very rare cases in which they are said to have been found, would of course be conclusive, but the utmost caution should be exercised, recollecting the great variety of shapes and sizes assumed by the epithelium of the urinary passages. The appearance of hæmaturia depends partly on the way in which the tumor invades the kidney, and on its increase in size. If growing in such a way as to compress the ureter in the early stages, before any erosion of the mucous membrane has taken place, blood even if set free in the pelvis, cannot reach the bladder. If hæmaturia is present before any tumor can be felt, it has only a subordinate value, but if occurring after the discovery of such tumor, the combination is of the highest significance. Pain is complained of in almost all cases and is situated in the loin and abdomen, and may radiate down the front of the thigh. The presence of a tumor is a very significant symptom. Minges found a tumor absent only three times in one hundred and three cases, and in two of these, a tumor was not discovered because it was not looked for carefully. The tumor is solid, resisting to the touch, generally but slightly movable; yet I know of two cases seen by Prof. Osler in which the tumor was very movable; if the abdominal walls are thin and the tumor large, its anterior surface may be satisfactorily palpated and may be found to be irregular. It is situated in the loin, and extends backwards, filling up the lumbar hollow, then grows forward and downward. Usually the hollow in the loin is still preserved; inspection of the back therefore without palpation, is not of much assistance in making a diagnosis. Renal tumors may be diagnosed from hepatic and splenic enlargements, with which they are most likely to be confounded, by their being rounded on all sides when exposed to the fingers, and not notched or presenting a sharp edge. Hepatic tumors are flat upon percussion anteriorly, while tumors of the kidney are resonant, unless the ascending or descending colon is displaced laterally by the growth, in which event resonance could be obtained in the flank. Splenic tumors like hepatic, are flat upon percussion in front, and there is not to be detected an area of resonance between the tumor and the ribs, which is present when

[1] A paper read before the Pennsylvania State Medical Society, June 6, 1888.

the left kidney is the seat of a tumor. Renal tumors are more likely to be mistaken for tumors of the ovaries, but here the history of the case, a careful examination of the abdominal walls and an examination per vaginam and rectum will in the majority of cases enable us to make a differential diagnosis.

Before proceeding to remove a diseased kidney, it is prudent to learn, if possible, the condition of the other organ; but this is especially important when contemplating the removal of a suppurating kidney, as in these cases the disease nearly always originates in the bladder and extending upwards, is more likely to involve both organs than is the case in malignant disease of the kidney.

Many devices have been introduced with the object of determining the condition of the other kidney, but as yet, none of these is entirely satisfactory, or, I venture to say, practicable, in the male subject. In the female, by dilating the urethra, either ureter can be catheterized without much difficulty; thus we are able to obtain a specimen of the urine secreted by the opposite kidney, after examining which, we can reach a more positive conclusion. Greig Smith practices incision of the outer urethra, and dilatation of the inner urethra and neck of the bladder, in the case of the female. The additional freedom in exploring the bladder so afforded, is much greater than would be supposed.

Nephrectomy on the living subject was first performed as a premeditated operation by Gustav Simon, of Heidelberg, in April, 1869. Three different surgeons had preceded Simon in excising the human kidney; but without knowing the nature of the tumors they were removing until the operation had been completed. The first of these operations was performed in 1861, the others in 1867 and 1868. The ventral method was employed in each, and all died. Simon's case was the fourth in which nephrectomy was performed, and the first in which the lumbar method was adopted. The patient recovered. Since that time the operation has been performed a number of times.

The different operations for the removal of the kidney are lumbar nephrectomy and removal by abdominal section; the section can be made either through the linea alba or the semi-lunar line. For the removal of new growths of the kidney, the lumbar operation would only be entertained when the tumor is small. By abdominal section we have better access to the organ, and are thus better able to deal with adhesions and the pedicle; at the same time the opposite kidney can be examined. In favor of the lumbar operation is the fact that we do not wound the peritoneum, and are supposed to have better drainage; but by using the glass drainage-tubes, with the cotton rope, the drainage after abdominal section is quite as satisfactory as after the lumbar operation.

Dr. S. W. Gross's statistics up to April, 1885, show that the kidney has been removed for sarcoma thirty-three times, with fourteen recoveries and nineteen deaths, mortality 57.57 per cent. Of twenty-six operations by abdominal section, 11 recovered and fifteen died, mortality 57.69 per cent. Of seven operations by lumbar nephrectomy, three recovered and four died: 57.14 per cent. Of fourteen survivors six subsequently died, five from metastasis, one from an unknown cause, while one was living with recurrence at the end of four months; five were well at the end respectively, of 17, 22, 23, 35 months and five years. For carcinoma in fourteen cases, four recovered and ten died: 71.42 per cent. nine abdominal sections with one exception, were fatal; in one of the four lumbar operations the patient died, and three recovered; another nephrectomy, it is not known what operation was used, resulted fatally; of the four survivors, two died of secondary growths at the expiration respectively of forty-four days and two months, and the remaining two were alive at the end respectively, of two months and thirteen months. There were then fourteen recoveries from sarcoma and four from carcinoma, making a total of eighteen recoveries from operations. Of the eighteen persons, therefore, who recovered from the operations, only two can be regarded as cured; for only two, both of whom had suffered from sarcoma, were alive and well at the end of three years after the operation. For benign tumors, four nephrectomies were done, with three recoveries and one death.

On March 11, 1888, Dr. Isaac Leopold was urgently called to see Mrs. S. T., suffering with an attack of hæmaturia, when the following history was elicited: Widow, 41½ years old, married twice, no children, several abortions, the result of her own exertions; family history good. Says that six years previously in 1882, she was operated upon for a vesical calculus, and at that time her physician told her she was getting a tumor, but she refused to believe it and continued at her work. March 11, 1888, present condition: passes no urine for twenty-four hours, then passes a large amount of bloody urine containing large clots, the blood amounting to over one pint. By examina-

tion with the sound, no vesical calculus could be found, nor could any evidence of tumor of the bladder be detected; uterus and appendages normal. On examination of the abdomen, a large hard mass was found, situated anteriorly on the left side, and filling the left lumbar and inguinal, and extending into the hypogastic and umbilical regions, two inches to the left side of median line. The tumor felt hard and was slightly movable, giving no evidence of fluctuation upon percussion; the flank was absolutely flat. Tympanitic resonance in front and above the tumor. Diagnosis of malignant disease of the left kidney was made. The patient was told the nature of her trouble and, with the administration of ergot, was ordered to quit work, to rest in bed, and was further advised to have a consultation, which latter she refused. March 12, hemorrhage had ceased, urine nearly clear, containing a very small amount of organized clot, specific gravity 1022, slight trace of albumin, no tube casts, large amount of epithelium from the bladder, and some that appeared to have come from the pelvis of the ureter. Her condition continued to improve until between March 12 and April 5 the patient had a slight hemorrhage, but Dr. Leopold was not sent for, the patient controlling it herself with the ergot which the doctor had left. April 5 she had another severe hemorrhage, when Dr. Leopold was sent for and again advised a consultation, to which the patient consented, and I was asked to see her with Dr. Leopold; when I fully concurred with him as to the nature of the case and advised operation. April 7, the patient had another severe hemorrhage, passed half a pint of blood. April 8, she was removed to a private room in St. Joseph's Hospital, and after the exertion consequent upon the journey, had three small hemorrhages. April 9, Prof. Jas. Tyson saw her with Dr. Leopold and me, and fully agreed with us as to the nature of the case. The patient remained in bed, the urine continuing to show slight traces of blood, till April 13, at 1 P.M., when nephrectomy was performed.

Description of the Operation of Nephrectomy through the Abdominal Wall, anteriorly, after the manner of Langenbuch.

After the patient had been etherized, having also been subjected to the ordinary antiseptic preparation, the left kidney being the seat of the growth, an incision five (5) inches long, not extending high enough to endanger the wounding of the attachment of the diaphragm, was made through the left linea semi-lunaris; the peritoneum being reached, was opened, and a large flat sponge inserted to prevent the escape of the small intestines, after which the descending colon and the medium through which it is attached to the posterior wall of the abdominal cavity, namely, the descending meso-colon, was brought into view, when its external layer was divided to an extent corresponding in length to the wound in the abdominal wall anteriorly, thus exposing the anterior surface of the growth and giving access to the left retro-peritoneal space, which space is occupied normally by the left kidney. The object in selecting the external layer of the descending meso-colon in preference to the internal layer, is the avoidance of injuring the blood-vessels supplying the colon, thereby lessening the likelihood to necrosis of a portion of the gut. The next step in the operation was by far the most tedious, as well as difficult, namely, the breaking up of the adhesions, the growth being most intimately adherent at all points of its surface, and the exposure of the pedicle consisting of the ureter, renal artery and renal vein. In breaking up the adhesions, it required great care not to tear through the internal layer of the descending meso-colon and the inferior layer of the transverse meso-colon, which latter separates the left kidney from the spleen, both of which layers of the peritoneum were found intact at the autopsy. When the growth was freed almost up to the point of attachment to the pedicle, a stout silk ligature was thrown loosely around the pedicle, in the event that if any part of it were torn, to give immediate means to arrest any bleeding that might be the result by simply tightening the ligature. After the completion of the separation of the adhesions, the pedicle was grasped close to its attachment to the growth by a pair of Spencer Wells' pedicle forceps, and tied with a strong silk ligature *en masse* immediately beneath the forceps; the growth was cut away, then the pedicle separated below the ligature into two portions, the vein as one, the artery and ureter as the other, each of which was included in a single silk ligature. The object in separating the vessels, the artery from the vein, being to prevent the probability of the formation of an arterio-venous wound. The next step was the toilet of the peritoneum, which was made with hot distilled water, the introduction of a glass drainage-tube, the repositing of the descending colon, which during the operation was drawn toward the middle line, the rearranging of the small intestines in their proper position, as well as

the great omentum, the introduction of six (6) deep silk sutures and the dressing of the wound. The patient died twenty-four hours after the operation, never having rallied from the shock.

The autopsy, made three hours after death, showed the edges of the wound glued together, requiring quite a little force to separate them, the peritoneum healthy, the great omentum, the small intestines and the descending colon in their normal position. The stump was perfectly dry, as was also the retro-peritoneal space, there being a considerable deposit of lymph occupying this site. The right kidney slightly atrophied and fattily degenerated, otherwise normal. The heart, small and concentrically hypertrophied.

Dr. George Dock, who examined the tumor, made the following report:

Dear Doctor:—On examining the tumor referred to me by you, I find it of an irregular oval form, ten inches in length by five inches in width. The surface is smooth for the most part, of a dark red color; the consistency is firm, except at the larger end, where a soft, semi-fluctuating mass may be felt. At one end (upper and inner) is part of the pelvis of the kidney. On cutting open the tumor, part of the kidney can be seen at the end corresponding to the pelvis. Only a small part of the cortex and more than half the pyramidal substance can be recognized. The great mass of the tumor is composed of a soft, reticulated tissue, interspersed with masses of necrotic material. In the larger end is an irregular mass of clotted blood the size of an orange. The capsule is thickened in some places, and fibrous bands pass from it into the substance of the tumor. Thin sections of the tumor taken from various parts show it to be made up of large and small alveoli filled with cells. The cells have large nuclei and a large amount of clear protoplasm. Most of them are fatty degenerated. In many of the alveoli the cells along the wall have an arrangement suggesting that of the convoluted tubules of the kidney. Blood corpuscles fill the centres of many of the alveoli. The thickened parts of the capsule have the same structure as that just described, but the alveoli are smaller, and the walls are thicker. This growth passes gradually into the substance of the kidney, which shows hemorrhages into the tubules and slight fatty degeneration of the epithelium.

The growth is to be classed as a carcinoma of the medullary type, which has probably originated in the epithelium of the cortex.

Yours sincerely, GEORGE DOCK, M.D.

The conclusions at which I arrive are:

First. Sarcoma of the kidney in children contra-indicates operation.

Second. Sarcoma of the kidney in the adult is a justifiable cause for operation.

Third. Carcinoma of the kidney in the adult, unless coming under the surgeon's notice very early, contraindicates operation.

Fourth. Malignant growths of the kidney in the majority of cases should be removed by abdominal section, after the manner of Langenbuch.

Fifth. Benign growths of the kidney are cases for the lumbar operation, but when too large to be delivered *en masse*, should be removed in sections, the precaution being taken to ligature the pedicle before cutting away a section of the tumor.

It is probable, states Morris, that renal sarcoma in children, as also cancer at any period of life, will by future experience be excluded from the category of "cases for nephrectomy" performed by any method. In cancerous tumors it is not likely that life can be greatly prolonged, unless in the exceptional case in which the disease is detected before it has long existed, or has affected the lymphatic system.

CASE OF ELEVEN COMPOUND FRACTURES, WITH COMPOUND DISLOCATION OF SHOULDER; COMPLETE RECOVERY.

BY D. BENJAMIN, M.D.,
SURGEON TO COOPER HOSPITAL, CAMDEN, N. J.

J. M., 32 years old, a large, well-built white brakeman on a railroad, fell under a freight car on the night of December 7, 1886. Examination thirty minutes after the accident showed a compound fracture of the first phalanx of the thumb, of the first, second, third and fourth metacarpal bones, and of the first phalanges of the first, second, third and fourth fingers of the right hand; also a compound fracture of the left humerus in the upper third, and a compound dislocation of the head of the left humerus, and a simple fracture of the left clavicle. The left lung was contused (bloody expectoration), and there was great contusion of the left upper part of thorax, front and back. The watch which was found in the man's left vest pocket had its case and works smashed, indicating that the left side had been severely compressed.

The patient was taken home, and his wounds were dressed and the fractures all reduced, after which he was kept perfectly

quiet on his back upon a mattress. The left arm and shoulder were treated with paste-board external and internal splints with shoulder-cap. The circulation in the right hand and fingers was so poor, from local injuries to the blood-vessels, that a bandage could not be applied sufficiently tight to keep the fractures reduced, without imminent danger of mortification of the fingers, and of a large portion of the hand. The hand was treated on a large, flat board splint (not paste-board); a large piece of oakum was placed in the palm of the hand, and the fingers were left flexed, owing to the fact that straightening them increased tension on the parts and interfered with the circulation, and would necessitate more pressure from the bandage to hold them in place. All the open wounds were closed with sutures, the wounds washed with carbolized oil, and patent-lint dressing applied. During the first week the patient's temperature reached 101°, his pulse 118; crepitation developed in his left lung, and he was troubled with cough and slight spitting of blood. After the eighth day the temperature and pulse gradually declined, and became normal about the fifth week. The wounds were disturbed as little as possible; but considerable suppuration about the left shoulder joint compelled frequent cleansing about that part.

The medical treatment consisted the first few days of anodynes and diaphoretics, and afterwards of an occasional saline cathartic and Basham's mixture. The patient was able to sit up by the latter part of the second month, and made a complete recovery with the exception of a slight deformity of the first metacarpal bone of the right hand, which, however, gives him no inconvenience.

He is now employed as a piano mover, and has perfect use of both arms.

—A rare example of patent ductus arteriosus in a woman, thirty-six years old, was shown by Dr. H. M. Murray at a recent meeting of the Pathological Society of London. The cause of death was ulcerative endocarditis, and during her life the patient was neither cyanosed nor affected with clubbing of the fingers. The ductus was three-eighths of an inch long, and admitted a quill; vegetations in large quantity existed near its opening into the pulmonary artery, into which, however, blood passed, as was shown by the presence of a distinct thrill and murmur during life. —*Medical Press and Circular*, May 9, 1888.

Society Reports.

PENNSYLVANIA STATE MEDICAL SOCIETY.

THIRTY-NINTH ANNUAL SESSION, AT PHILADELPHIA, JUNE 5, 6, 7, 8, 1888.

Second Day, Wednesday, June 6.

MORNING SESSION.

After the announcement of the delegates who had been selected as members of the Nominating Committee,

Dr. R. J. Levis, of Philadelphia, delivered the

President's Address,

on "The Traditional Errors of Surgery." After tracing recent history of the science he declared that hope might be entertained that the millennium of the art would soon arrive. The advance in late years had been in rapid ratio compared with that of the knowledge gained in the past. Error had been to a very great degree promoted by prejudice, he said, and too much teaching had been accepted from the Old World. This was done even at the present time, when American science in general surgery is equal to or in advance of that of any other nation. One error calling for immediate correction was the use in some colleges of English text-books in preference to those of American writers, when the latter are in many respects far superior to those of foreign authors.

He advocated the antiseptic treatment recommended by Sir Joseph Lister. In the general adoption of antiseptic treatment he gave credit to the younger men of the profession, whom he characterized as the pioneers in the movement. The only benefit in traditional errors is that they may lead to the discovery of important remedies and bring reform and truth.

Dr. R. Lowry Sibbet, of Carlisle, read a paper entitled:

A Brief Review of the Decisions of the Courts concerning the Registration Act of 1881.

He reviewed the decisions of the different courts in administering the Registration act of 1881. In summing up he said that the great trouble was too much registration, and asserted that the prothonotaries were responsible for this, and that if the act was intelligently executed a rapid decrease of fraud would result. He warmly advocated the appointment of a State Board of Medical Examiners.

Dr. John H. Packard, of Philadelphia, followed with a paper entitled:

The Proposed State Board of Medical Examiners.

He objected to the appointment of a State Board of Examiners, because it would put the homœopathic and other schools of the profession on an equal footing with the regular school.

Considerable discussion followed the reading of these papers, most of it being favorable to the idea of having licenses to practice issued only by a State Board of Examiners. Incidentally, the resolutions in the report read at Tuesday's session, by Dr. Jackson, were brought forward, but they did not come to a vote because parliamentary law prevented their consideration until after the scientific discussions were concluded.

The next paper was one by Dr. L. F. Flick, of Philadelphia, on

Contagiousness of Phthisis.

In this paper Dr. Flick stated, as the result of a careful and prolonged study of the appearance and distribution of phthisis in the fifth ward, in Philadelphia, his conviction that phthisis is a contagious and infectious disease.

In the discussion which followed, Dr. O. G. Given, of the Carlisle Indian School, spoke of the errors to be found in many of the statistics in regard to phthisis among the Indians, and denied that the frequency and fatality of phthisis is increasing among pure-blooded Indians.

Dr. F. P. Henry, of Philadelphia, pointed out the erroneous conclusions to which one might be led who assumed a causal relation between things which were merely associated. He instanced syphilis which is very common among sailors, who spend most of their time at sea and on ships; from which, he said, it would not be safe to deduce the proposition that syphilis is caused by sea-air and infects ships.

Dr. E. T. Bruen, of Philadelphia, said that he thought that there was much to be said in favor of the opinion that phthisis is contagious to a certain extent. The results of pathological experiment and clinical experience will, he thinks, convince one who studies the subject carefully that there is more in this theory than would appear at first sight.

Dr. T. J. Mays, of Philadelphia, followed with an elaborate and thoughtful review of many of the points raised by Dr. Flick, and of the assertions upon which they rested. Dr. Mays strongly opposed the idea that tuberculosis is contagious, in the ordinary sense of the word, and pointed out the peculiarities in the mode of development and the distribution of phthisis which are inconsistent with the theory that it is contagious. He quoted interesting reports and statistics in confirmation of this view, and laid special stress upon the utter failure of the attempt to limit the ravages of consumption in Naples by Government regulations adopted on the theory that the disease is contagious.

Dr. C. R. Earley, of Ridgway, spoke against the idea that tuberculosis is contagious and cited his experience as a practitioner for forty-three years as having furnished not a single case in which he could attribute the appearance of phthisis to contagion. He begged the members of the Society to bear in mind their own experience when they listened to the papers of gentlemen who maintained that consumption is contagious. For his own part he did not believe that this view was correct.

Dr. Traill Green, of Easton followed with the opinion he had formed from his own experience which now covered the greater part of a century, and pointed to himself as an illustration of the fact that one might have a mother die of consumption, and himself live many years in health and vigor, although for several years of his early life associating intimately with a consumptive. He did not believe that consumption is contagious and hoped that the Society would not commit itself to such a belief.

The interim between the morning and afternoon sessions was occupied by a clinic at the Pennsylvania Hospital by Dr. John Ashhurst, Jr., followed by a luncheon tendered by the managers of the hospital, and a lunch given at the Union League by the Faculty of the Medico-Chirurgical College.

AFTERNOON SESSION.

At the afternoon session, the nominating committee reported the following persons for officers for the ensuing year: President, J. B. Murdock, of Allegheny county; Vice-Presidents, L. H. Taylor, of Luzerne county; Benjamin Lee, of Philadelphia; W. W. Dale, of Cumberland county; W. S. Roland, of York county; Permanent Secretary, William B. Atkinson, of Philadelphia; Recording Secretary, Charles W. Dulles, of Philadelphia; Corresponding Secretary, J. H. Musser, of Philadelphia; Treasurer, O. H. Allis, of Philadelphia;

Committee on Publication: Ed. Jackson, chairman, Philadelphia; G. W. Guthrie, Wilkes-Barre; S. H. Gump, Bedford.

Judicial Council: Horatio C. Wood,

Philadelphia; J. S. Carpenter, Schuylkill county; L. H. Taylor, Luzerne county.

Time and place of next meeting, third Tuesday in May, 1889, in Pittsburgh.

Chairman of Committee on Arrangements, E. A. Wood.

The report was adopted.

Dr. Theophilus Parvin, of Philadelphia, then read the annual

Address on Obstetrics.

Dr. Joseph Price then made some remarks on

Pelvic Surgery by Abdominal Section,

in which he described the method exhibited by Dr. L. Senn, of Milwaukee, at the last meeting of the American Medical Association, for determining the existence and location of perforations of the bowel in case of pistol-shot wounds of the abdomen. The remarks were illustrated by an experiment of great interest and brilliancy. A dog was etherized and shot in the abdomen. Then the intestine was inflated per rectum with carburetted hydrogen gas, and a flame was applied at the opening in the abdomen. When this caused a minute explosion upon ignition of carburetted hydrogen escaping from it, the abdomen was opened by Dr. C. B. Penrose, and the perforation of the bowel was found in the upper part of the small intestine.

Dr. Mordecai Price then read a very interesting paper on

Removal of Kidney for Traumatism,

illustrated by presentation to the Society of the pistol, the bullet, the ligature, and the patient concerned. The case was one of pistol-shot wound of the abdomen in a little girl. The ball passed through the liver and wounded the right kidney. The operation consisted in opening the abdomen and removing the kidney. The recovery was excellent, so far as the nephrectomy was concerned, although there was long-continued suppuration in the wounded liver.

Dr. John B. Deaver, of Philadelphia, then read a paper on

Nephrectomy for New Growths,

which is published in full in this issue of the Reporter (see p. 772.)

Dr. S. T. Davis, of Lancaster, then read a paper on the

Removal of the Uterine Appendages; with Report of a Case,

which will be published in the next number of the Reporter.

A paper by Dr. C. B. Penrose, of Philadelphia, on

Pyosalpinx and Pelvic Abscess

was read by title and referred to the Publication Committee.

Dr. John H. Musser then read a paper entitled

Memoranda of the Life and Character of Benjamin Rush.

This paper contained an earnest eulogium of the character and attainments of Dr. Rush and a recommendation that the Pennsylvania Medical Society undertake the republication of Dr. Rush's medical works.

Dr. E. A. Wood then spoke enthusiastically upon the fame and deserts of Dr. Rush, and moved that Dr. George H. Rohé, of Baltimore, Secretary of the Rush Monument Fund, be invited to address the Society. The motion being unanimously carried,

Dr. Rohé then addressed the meeting and advocated the claims of the Rush Monument Association upon the consideration of Pennsylvania medical men.

Dr. Frederick P. Henry then read a communication from the Standing Committee of Visitors of the Asylums for the Insane in Philadelphia County, for himself and his associates on the Committee, Dr. E. T. Bruen and Dr. Alfred Whelen.

Dr. W. F. Waugh, of Philadelphia, read a paper on the

Specific Treatment of Typhoid Fever,

in which he described the benefits which he had derived from the use of sulpho-carbolate of zinc, in the treatment of summer complaint, and the way in which he came to use it for its antiseptic effect in typhoid fever. He spoke of his experience with this drug in eight cases of undoubted fever, which leads him to believe that it is one of great value in this disease.

Dr. T. D. Dunn, of West Chester, then read an interesting paper on the

Hypodermic Use of Hydrochlorate of Cocaine in Migraine and Spasmodic Asthma.

Dr. James Tyson corroborated the statement of Dr. Dunn in regard to the beneficial influence of the treatment in some of the cases mentioned.

Dr. Nancrede spoke of the occurrence of dangerous symptoms in two recent cases in Philadelphia, with death in one.

Dr. J. T. Carpenter, of Pottsville, spoke of a similar experience in which grave symptoms of collapse followed the use of cocaine.

Dr. Thomas, of Pittsburgh, spoke of the fact that the results attributed to cocaine may have been due to shock or nervous impression.

Dr. Daly uses weak solutions in treating nasal diseases, and thinks as good effects can be secured from them as from strong solutions.

Dr. Earley asked for indications for the use of cocaine.

Dr. Dunn said it was used only in severe cases, such as are described by Hughlings-Jackson under the title "nerve-storm." He knows of only four cases of death from the use of cocaine, although there seems to be such a thing as idiosyncrasy in regard to it.

Dr. C. H. Thomas referred to the experience of Drs. Thomas Evans and Arthur C. Hugenschmidt, of Paris, in the use of cocaine for the painless removal of teeth.

Dr. Tyson related the history of a case in which a solution of cocaine injected into the bladder produced symptoms which plainly indicate that it was absorbed.

Third Day, Thursday, June 7.

Dr. H. C. Wood, of Philadelphia, read the

Address in Mental Disorders,

which is published in this number of the Reporter (see p. 767). At the conclusion Dr. Wood presented the following resolution:

Resolved, That the President be directed to appoint a Committee which shall confer with the State Committee on Lunacy, and if in the concurrent opinion of the two committees any changes are advisable in our laws relating to lunacy, shall have the power to represent this body in obtaining such legislation.

Dr. J. Chris. Lange, of Pittsburgh, then read an elaborate paper on

Some Influences of Disease upon the Mind.

A paper by Dr. Hoyt, of Philadelphia, was read by title.

After the reading of this paper Dr. James McCann, of Pittsburgh, delivered the

Address in Surgery,

In which he said that the most remarkable and important advance in surgery had been in operations on the brain, and detailed several forms of operating which have been proved to be practicable and useful.

The discussion on Dr. Packard's resolution regarding the Committee on Medical Education was then taken up.

Dr. Flick strongly opposed Dr. Packard's substitute, which referred the whole matter to the Judicial Council for inquiry in regard to its conformity with the code of ethics.

Dr. J. B. Roberts also opposed Dr. Packard's substitute, and cited acts of the State Society and American Medical Association sustaining his opinion.

Dr. S. S. Cohen made the point of order, that the Society had twice passed upon the question of ethics involved by the previous approval of the resolution, and that Dr. Packard's resolution was not in order. The Chair decided the point of order well taken.

The resolution introduced by Dr. Jackson was then taken up, and after an animated discussion was finally passed.

Dr. J. V. Shoemaker, of Philadelphia, gave an outline of a paper on the

Cause and Treatment of Psoriasis,

And exhibited a patient.

During the noon recess Dr. S. W. Gross gave a clinical lecture on aseptic surgery, at the Jefferson Medical College Hospital, after which a luncheon was given the delegates in the college building.

AFTERNOON SESSION.

Dr. B. Alexander Randall, of Philadelphia, delivered the

Address in Otology,

in the course of which he asserted that the treatment of ear diseases constitutes about two per cent. of all the work of the physician. In Philadelphia there are 400 deaf mutes in the Institution for the Deaf and Dumb and about 1000 outside of the schools. If we ask the cause of deafness in these deaf mutes the answer is one that challenges attention. While the census returns set down rather more than half of the cases as congenital, more careful and thorough inquiries show that in sixty per cent. of the cases the deafness is acquired. Of some 9000 instances where the cause has been clearly ascertained, more than one-third are ascribed to scarlet-fever and measles. Among pupils in the public schools, from thirteen to twenty-five per cent. have been found with hearing less than one-third of the normal in one ear, and some seven per cent. less than one-third in both ears.

Dr. L. J. Lautenbach, of Philadelphia, read a paper on

Prevention of Ear Disease.

Colds, he said, are among the most frequent causes of ear troubles, especially those produced by leaving the head uncovered when overheated. The low-necked and sleeveless dresses of women and the evening dress of men are fruitful causes of diseases of the ear. During the fevers of childhood attention should be given to any inflammation of the throat, with a view of preventing

the danger of evil effects on the ear. The frequent washing of the interior of the ear is to be avoided, as nature provides for its cleansing by the expulsion of the wax, and swimmers should always put cotton in their ears to prevent the entrance of water. The boxing or pulling of children's ears is often attended by the most serious troubles. A most frequent cause of ear disease, especially in the young, is the absorption of nicotine from smoking tobacco, and children under 18 years should, for this reason, never be allowed to smoke.

Dr. C. H. Burnett, of Philadelphia, followed with an interesting paper on

Aural Vertigo,

and illustrated his views in regard to it by a demonstration with an imitation middle ear.

Dr. Harrison Allen, of Philadelphia, then read a carefully prepared study of

Gouty Sore Throat,

giving a description of its principal characteristics as illustrated in a number of cases which had come under his notice.

A paper by Dr. Charles H. Thomas, of Philadelphia, on

Nervous Reflexes from Eye-Strain

was then read by title.

After this the society voted to allow Dr. J. William White, of Philadelphia, to read a paper on

Operation for the Radical Cure of Strangulated Hernia,

and to exhibit two patients upon whom he had performed this operation with success.

Dr. H. F. Hansell, of Philadelphia, read a paper on

Insufficiency of the Internal Recti-Muscles.

Dr. A. G. Heyl, of Philadelphia, followed with a paper on

Two New Retinal Symptoms of Brain Disease.

Dr. Heyl called attention to the close connection between the retinal and intra-cranial circulation, and to the probability that disturbances in the latter could be recognized by the ophthalmoscope. Two abnormalities in the retinal circulation illustrating this point were then described. 1. The injection of a series of fine vessels coming off at right angles to the main retinal trunks, invisible in normal conditions. The injection causes them to become visible with the ophthalmoscope, and occurs in congested states of the meninges of the convexity of the brain. 2. An abnormal decrease in calibre of the dichomotous branches of a retinal artery. This was noticed in cases of slight mental weakness, characterized by rambling talk, loss of memory, lack of mental grasp. Cases were cited to show that the phenomenon was associated with abnormal ventricular pressure in the brain, and was probably due to an abnormal state of the large vascular trunks at the base of the brain.

Dr. Charles W. Dulles, of Philadelphia, then read a

Report on Hydrophobia,

in which he stated that the method of Pasteur had attracted much less attention during the last year than ever before, and that it seemed to be in a fair way to die a natural death. He said that the figures within his reach indicate that Pasteur practiced his method during the whole of last year only about as often as he was practicing it every month a year ago.

He showed that the effect of the method had not been to diminish the mortality from hydrophobia in Paris, for more deaths occurred in that city during the year 1887 than during 1880, 1883, 1884 or 1886. Two of the deaths occurred in persons who had been treated by Pasteur. They were explained on the ground that the method had not been thoroughly carried out in these cases.

He then submitted a brief outline of the cases occurring in the United States during the year since the Society last met, of which he had heen able to obtain any account. The cases numbered only fifteen for the whole United States—a very small number for the population, and very much smaller without Pasteur's method than had occurred in France with Pasteur's method. He desired to call attention to the principal points which had impressed him in studying the cases of the last year. Among these was the fact that the diagnosis of hydrophobia is rarely made in the first instance by the physician, but is usually only a confirmation of the diagnosis made by the laity. He also spoke strongly against the use of testing with water to determine the hydrophobic nature of the disease, and the use of forcible restraint and narcotics in its treatment.

In concluding, he expressed the hope that in time the belief in hydrophobia as a specific disease would disappear from the earth as the belief in witchcraft—which once had the support of Church and State, of the medical profession and the laity—had disappeared. He called attention to the fact that there had not been a single case of hydrophobia reported in the State of Pennsylvania during

the year just ended, and was inclined to believe that this fact had some relation to the fact that the physicians of this State are free from superstition in regard to this subject.

Dr. E. O. Shakespeare, of Philadelphia, opened the discussion, strongly opposing the opinions expressed by Dr. Dulles, and ridiculing the source of his views as "antiquarian literature." He maintained that laboratory experiments were necessary in order to determine the nature of hydrophobia. He thought that an opinion founded upon clinical observation and a study of the literature of the subject did not warrant the formation of positive opinions, but that laboratory experiments were essential to understanding it. He supported the theories of Pasteur, and claimed that rabies was analogous to other diseases communicated from the lower animals to man, and that it could no more be denied than could the communication of anthrax.

Dr. Traill Green, of Easton, supported the opinions of Dr. Dulles, and hoped he would continue to investigate the subject and report to the Society. He said he had lived a long time, and had very little faith in the current belief in regard to hydrophobia, and thought it to be the duty of physicians to allay popular fears and not to excite them.

Dr. Rahter, of Harrisburg, described the history of a case which he treated in 1870, in the person of a girl sixteen years old, which he thought could not be explained, except on the theory that hydrophobia is a communicable disease.

Dr. Charles K. Mills, of Philadelphia, referred to his investigations in regard to hydrophobia, and stated that a careful study of the details of about a dozen cases which came under his notice had led him to believe that there was not one in which the symptoms could not be more easily and rationally explained than on the basis of a belief in the specific nature of hydrophobia.

Dr. Frank Woodbury, of Philadelphia, expressed his conviction that the specific nature of hydrophobia might be regarded as one of the things that are absolutely settled in medicine. He thought the cases to be rare, but had no doubt that they occur.

Dr. Dulles closed the discussion by denying the claim of Dr. Shakespeare that clinical observation and a study of the literature of a subject do not justify the formation of a scientific opinion in regard to it, and repudiating the dictation which sometimes comes from the laboratory men to the men engaged in the practice of medicine. He pointed out, in regard to the assumption that because anthrax is communicated to a man from the lower animals, therefore rabies is so communicated; that in every disease except rabies such communication carries with it the unmistakeable signs of the disease to which it is referred; but in hydrophobia we have a disease, attributed to the inoculation of rabies, which has diametrically opposite symptoms.

After the discussion was ended, Dr. C. H. Thomas moved that Dr. Dulles be requested to continue his studies in regard to hydrophobia and to report to the Society at its next meeting, and that Dr. Shakespeare be requested to prepare and lay before the Society a paper on the evidence for and manner of propagation of rabies and hydrophobia.

This motion was adopted.

Dr. Goodwillie, of New York, then gave, by invitation, a demonstration of his method of operating in cases of cleft palate and hare lip, which was listened to with marked attention.

Appointments by the President.

The President announced that the annual addresses at the next meeting would be delivered as follows: *In Medicine*, Dr. J. C. Wilson, Philadelphia; *Surgery*, Dr. John B. Roberts, of Philadelphia; *Obstetrics*, Dr. Francis N. Baker, Delaware; *Hygiene*, Dr. Thomas J. Mays, Philadelphia; *Mental Disorders*, Dr. Alice Bennett, Montgomery; *Laryngology*, Dr. W. H. Daly, Allegheny.

He also announced the following committees:

On State Board of Medical Examiners—Dr. L. F. Flick, Dr. Edward Jackson and Dr. W. F. Waugh, Philadelphia; Dr. E. A. Wood, Allegheny; Dr. L. H. Taylor, Luzerne.

On Pharmacy—Dr. J. W. Holland, Dr. L. Wolff, Dr. Ida V. Reel, Dr. H. Hamilton, Dr. J. G. Monnell.

On Clinical Research—Dr. John B. Roberts, Dr. J. H. Musser, Dr. Howard Allport, Dr. Thomas J. Dunn, Dr. L. H. Taylor, Dr. J. Z. Gerhard, Dr. B. C. Hirst, Dr. Rita E. Church, Dr. George Dock, Dr. Laura P. Hulme, Dr. Charles McIntyre, Dr. J. S. Carpenter, Dr. George Halberstadt, Jr., Dr. J. Madison Taylor, Secretary; Dr. F. A. Packard, Assistant Secretary.

Committee on Hospitals for the Insane.

Dr. E. A. Wood presented the following, which, he said, was satisfactory to both sides in the discussion regarding the management of hospitals for the insane on Tuesday, and which was adopted, viz.:

Whereas, the hospitals for the insane, under the care of the State of Pennsylvania,

are at present organized upon either of two radically differing plans, each claiming better results in the medical care of their inmates; be it

Resolved, That the President of this Society be directed to appoint a committee of thirteen persons, which is to include all the superintendents or chief physicians of such State hospitals, to investigate into the relative merits of the two systems, and report the results of their deliberations at the meeting of this Society in 1889.

The committee appointed is as follows: E. A. Ayres, Hiram Corson, John Curwen, H. C. Wood, S. S. Schultz, J. Z. Gerhard, R. H. Chase, Alice Bennett, G. B. Massey, Samuel Wolfe, John Fay, Traill Green, J. L. Stewart.

Committee to Revise the Constitution and By-Laws.

On the motion of DR. O. H. ALLIS, a committee, consisting of Drs. William M. Welch, W. H. Parish, L. K. Baldwin, of Philadelphia; E. A. Wood, of Pittsburg, and P. T. Eisenberg, of Montgomery county, was appointed to revise the constitution of the society and report next year.

DR. LAWRENCE TURNBULL presented a specimen of the entire labyrinth of the ear, removed from a patient.

Reception.

A reception was given the Society in the evening by the College of Physicians, at its hall, Thirteenth and Locust streets. In the absence in Europe of the President, Dr. S. Weir Mitchell, the honors were done for the college by the Vice-President, Dr. John H. Packard, assisted by a reception committee, of which Dr. R. A. Cleemann was chairman.

Fourth Day, Friday, June 8.

At the closing session the Society considered Dr. H. C. Wood's resolution to appoint a committee of three to confer with the State Lunacy Committee, and if in their concurrent opinion any changes are needed in the State Lunacy laws, to represent the Society in urging the requisite legislation.

After brief discussion the resolution was adopted.

DR. PACKARD then offered a resolution setting forth that in the sense of this body, the American Medical Association may by a vote set aside the code of ethics, and other medical societies may do likewise, and it is not in order for a member to call attention to any breach of the code of ethics.

This resolution was intended to mark Dr. Packard's opinion of the action of the Society the day before, when it was decided that he was out of order in moving to refer the matter concerning the appointment of a State Board of Medical Examiners to the Judicial Council, to decide a question of ethics. He insisted that he had been unjustly treated and the action was in contravention of law.

DR. JACKSON moved to lay the resolution on the table. The President stated that the action yesterday was apparently unanimously approved by the Society, and the motion to lay the resolution on the table was adopted.

DR. WOOD, of Pittsburgh, amused the Society by moving the adoption of a resolution that the President-elect shall take the following

"Hypocritic Oath:"

"Having been duly elected President of this Society, do you promise to hold the Pennsylvania Medical Society, as it has been held by many illustrious men, as a stepping-stone to success, as a round in the ladder of fame, as a lemon to be squeezed, as a lever to raise your hopes, as a block and tackle to exalt your ambition, as a peacock's feather in a jackdaw's tail, as a lion's skin on a sheep, a spur on knighthood's heel, a garter on the leg of a courtier, a medal on the breast of a hero, and a convenient method of advertising your business, and that as soon as your time expires you will forever after turn your back on it and ignore it. Selah!"

DR. WOOD, in closing, suggested that his resolution be referred to the "Committee on Canals and Inland Navigation."

DR. LEVIS suggested that it be referred to the Committee on Lunacy.

DR. TRAILL GREEN moved that the committee to investigate the management of State Hospitals for the Insane be authorized to confer with the Legislature. Carried.

DR. DULLES brought up the matter of publication of transactions, and asked if the Society desired to give any instructions to the Committee on Publication.

After some discussion, a motion by DR. BENJAMIN LEE was adopted, to rescind the resolution of instruction adopted at the meeting in 1887.

DR. HIRAM CORSON moved that memoirs of deceased members reported by the county societies be included in the published transactions. Carried.

DR. JACKSON moved that the Recording Secretary be authorized to employ a stenographer to report the proceedings of the next session of this Society. Agreed to.

On motion of DR. ULLOM, it was resolved that the newly elected officers be installed.

Dr. Levis, the retiring President, then made a short speech, thanking the members for their kindness and courtesy to the chair, and introduced his successor, Dr. Murdock, of Pittsburgh, who briefly expressed his thanks for the high, unsought and unhoped-for honor of occupying the office filled by such great and good men as John Atlee, Samuel D. Gross, Hiram Corson, and others. He assured the members that in Pittsburgh next year they would have a hearty Western welcome.

Dr. Traill Green moved that the thanks of the Society be given to all the officers, societies and persons who have been instrumental in entertaining the members in this city.

On motion, the Society adjourned to meet at Pittsburgh, May 21, 1889.

ILLINOIS STATE MEDICAL SOCIETY.

THIRTY-EIGHTH ANNUAL MEETING, HELD AT ROCK ISLAND, ILLINOIS, MAY 15 AND 16, 1888.

Second Day, Wednesday, May 16.

Antiseptic Obstetrics.

The Chairman of the Committee on Obstetrics Dr. C. W. Earle, desired to call attention to the following questions:

First.—Does the high rate of mortality still remain in the private practice of obstetrics?

Second.—Can the extreme low rate of mortality attained in hospital obstetric practice be attained in private practice?

Not many years ago Mr. Lawson Tait paid a visit to Prof. Tarnier, at la Maternité. The professor called the attention of Mr. Tait to a linear chart on the wall of his room, showing the total death-rate of women confined in that hospital from 1792 to 1886. This record is divided into three periods: (1) that of inaction, in which the mortality was from 9.3 to 20 per cent; (2) the battle of hygiene against infection and contagion with a mortality of 2.3; (3) the victory of antiseptics, with a mortality of less than 1 per cent, and in Tarnier pavilion since June, 1880, with 785 deliveries, not a death has taken place. About the year 1847, Semmelweiss wrote: "Puerperal fever has existed for two hundred years; it is time that it should disappear."

Concerning puerperal fever in ancient times we know but little. Litzman believes it should be classed among the modern diseases. But in 1664 it raged in the Hotel Dieu, in Dublin Maternity in 1672, and again in 1774 in Paris and Dublin, and up to the end of that century in Vienna, Berlin, Giessen, Copenhagen, and at St. Petersburg. In the last named place in 1825, one in eleven died. In Lombardy between 1786 and 1887, not a patient survived. In view of these facts we are not surprised that Semmelweiss declared that it was time that this murderous mortality should disappear. In 1870 to 1872, the influences of microbes in the etiology of disease began to be noticed, and in 1878 Pasteur began his investigations, from which we commence to collect data to prove what is now known as demonstrated in regard to germs. Previous to this, however, Tarnier demonstrated the contagiousness of puerperal fever by inoculation.

About 1880, Pasteur believed he saw the microbe of puerperal fever. It has been demonstrated that (1) the air and water of the earth are crowded with organized microscopic beings; (2) they live and multiply at the expense of organized matter; (3) their penetration into the tissues produces disease; (4) the skin, respiratory and digestive passages furnish the channels into the body; (5) a healthy tissue has never produced a microbe; (6) any abrasion of tissue against which these microbes come makes it possible for them to enter the system; (7) unless germs are brought from without there can be no infection; (8) many things in regard to their virulence, nature, contagion, age, and development, are yet under consideration. The application of these principles has given the victory to antiseptics in hospitals.

As soon as it is known that confinement of a patient is about to take place, Dr. Earle is in the habit of requiring her to take a warm bath, at the conclusion of which the lower part of her person is to be washed with carbolized water. It is also requested that one or two carbolized vaginal injections shall be taken during the first stage of her labor. The nurse should subscribe to certain rules of cleanliness, and have some knowledge of the etiology of puerperal disease. The lying-in chamber should be in a room where no infectious diseases have been treated, and all bed clothing should be prepared by boiling in a given per cent. of carbolized water. Do not select a mattress which is filthy for fear that a better and cleaner one will be soiled by blood and other discharges during confinement. Do not provide pieces of old comforters, the sanitary condition of which is problematical. Do not borrow syringe or bed-pan, and assure yourself that those you have are boiled or washed in hot water and thoroughly carbolized.

Dr. George Wheeler Jones, of Danville, read a paper on

Obstetrics.

During the past year very little, if anything of special importance, has occurred in this branch of medicine which could be called strictly new. There seems to be a general tendency to a return to primitive views and older methods, although these often disguised under new nomenclature or presented under circumstances which would imply the most startling originality in both conception and technique.

Cæsarean Section.—The propriety of this operation in a large proportion of cases usually relegated to craniotomy has been presented with arguments of so forcible a character as to demand the attention of every accoucheur, and to require of each one a thorough fitness and preparation for the operation which may be required of him at any hour, although happily it may never be. The line of reasoning in favor of the operation of abdominal section is directed largely toward the rights of the child in the case, and the duty which we may owe to the one as yet unborn. With the operation, as improved and modified by Saenger, the reduction of mortality of both mother and child has been so great as to make the preference for the abdominal section not a matter of question, but greatly one of choice to every conscientious obstetrician where there is reason to presume that the child is living; and the slight resulting injuries to the mother in case of her presumable recovery would suggest its extreme propriety, if not preference, where the fœtus is dead.

Conservative Obstetrics.—The tendency of the day and hour is more and more toward conservative obstetrics—place the patient in the best possible condition and let her alone. Crede takes such extreme grounds, and goes so far in this matter that he makes his diagnosis of position, condition and advancement of cases by external palpation and manipulation of the uterus through the walls of the belly, leaving the entire genitalia alone, as a region too sacred or too dreadful to justify or permit the digital approaches of even the most skillful and aseptic of conscientious priests officiating at the alter of life, and engaged in the services devolving upon him in the second stage of human biological development. That ordinary accoucheurs will ever reach this degree of skill, or that it is best they should, is open to very serious doubt. Indeed, the amount of injury possible to both mother and child by careless external manipulation is too great to justify the efforts, except at the hands of those exceptionally skilful.

An adherence to the general rules of which Crede is the exponent, along with carefully conducted asepsis, will reduce the proportion of cases of puerperal fever to so such a minimum as to make it relatively scarcely worth considering.

It has been many a day since Dr. Jones has seen any fever in the lying-in chamber worse than a simple malaria, easily controlled by a sharp and decisive course of treatment. He believes with Crede that intrauterine douching and curetting of the uterus after labor are unjustifiable procedures, excepting in cases where there are symptoms urgently demanding it, and which are familiar to all. To resort to intra-uterine management, as a rule, cannot receive too great condemnation. There was one line of action in the management of labor to which he desired to call special attention, as he attributed much success to its careful adoption and adaptation. One is often called to see a case in which labor seems to be in full progress: strong, active pains, especially inclined to be expulsive in character. The patient has been sick perhaps several hours, and the woman's friends desire the doctor to be there to do something to terminate matters. Hot drinks and a variety of other domestic things may have been already undertaken. An examination reveals a firm, slightly dilated os, with the presenting part and uterine segment well up in the pelvic outlet, the cervix occupying almost a central position. Dr. Jones at once places his patient in the right decubitus, carefully lifts the lower uterine segment into the left ilium, depressing the fundus to the right, gives a full dose of morphine, codeia or other anodyne, and tells the woman to go to sleep, and he will return for her baby some other time. In this way he might be sent for in ten or twenty-four hours, and maybe, not for a month. When he finds the first stage completed, or the woman, without doubt, up to her full term, he repeats the procedure, expecting all irregular action to subside, leaving nature to the discharge of her special and important duties, unembarrassed by an irritable nervous system, uncrippled by a malposed womb. His object is to put off labor to the last possible moment in all such cases with the expectation of having it terminate easily and satisfactorily to all concerned.

Treatment of Extrauterine Pregnancy.—The treatment of extrauterine pregnancy has been placed upon a firm basis, from which there will not soon be any departure. Electricity has robbed it of its terrors and

placed it within the group of readily curable conditions, for which physicians can not be too thankful.

Eclampsia has another antagonist in the form of veratrum viride, which drug is being boldly advanced as a specific by several reliable practitioners. It must be given fearlessly in full doses. Its action is that of a vasomotor paralyzant.
